ACKNOWLEDGEMENTS

The following people are recognized for their contributions of time and expertise during this study:

BAY AREA AIR QUALITY MANAGEMENT DISTRICT
Jerry Bovee, Manager of Source Test
Elaine Ko, Supervising Air Quality Engineer, Source Test Section
Eric Stevenson, Director of Meteorology and Measurement (retired)
David Fairley, Ph.D., Statistician (retired)
Linda Duca, Supervising Air Quality Inspector
Ron Pilkington, Supervising Air Quality Inspector (retired)
Pamela Leong, Director of Engineering
Adan Schwartz, Senior Counsel

Members of the Heavy Liquids Study Technical Working Group
Ron Ricks, Marathon Petroleum Company (retired)
Todd Tamura, Tamura Environmental Consulting

Members of the Western States Petroleum Association
Brent Eastep, Phillips 66 Company
Don Bristol, Phillips 66 Company
Christina McDowell, Marathon Petroleum Company (retired)
Todd Osterberg, Chevron Products Company
Shawn Lee, Chevron Products Company
Gordon Johnson, Martinez Refining Company
Kathy Wheeler, Martinez Refining Company (retired)
Sharon Shearer, Martinez Refining Company
Kim Ronan, Valero
Taryn Weir, Valero
Kevin Buchan, Western States Petroleum Association

ABSTRACT

Over the course of five years, the Bay Area Air Quality Management District conducted a joint study with five San Francisco Bay Area petroleum refineries and their trade association, Western States Petroleum Association. The objective of the study was to understand the average emissions rate of organic compounds from leaks of petroleum refinery components (valves, connectors, pumps, and pressure relief devices that relieve to atmosphere) handling materials with an initial boiling point greater than 302 degrees Fahrenheit.

Over 10,000 components were screened for equipment leaks using portable hydrocarbon analyzers that measured leak concentrations of organic compounds. From the screened components, 165 components had mass emissions measured. These measurements were used to develop regression equations using linear regression analysis. Correlations between mass emissions and screening measurements (on the logarithm scale), operating temperature, and operating pressure were considered. Because operating pressure information was missing from approximately 30 percent of the screened components, correlation equations were established only for screening and temperature measurements.

Regression equations were used to estimate emissions from all screened components. Statistical procedures (bootstrapping with replacement, simulation) were used to address measurement and sampling errors. Average emission factors by component type for connectors, valves, and pump seals were developed. There were an insufficient number of screened pressure relief devices that relieved to atmosphere to develop an average emission factor.

The emissions averages resulting from this study are lower than commonly used emission factors developed by the United States Environmental Protection Agency for components in heavy liquid service.

Table of Contents

List of Figures

List of Tables

Acronyms

Abbreviation	Explanation
API	American Petroleum Institute
ASTM	ASTM, International (formerly American Society for Testing and Materials)
BAAQMD	Bay Area Air Quality Management District
CAPCOA	California Air Pollution Control Officers Association
CFR	Code of Federal Regulations
EPA	United States Environmental Protection Agency
FID	Flame ionization device
LDAR	Leak detection and repair
LOD	Limit of detection
OVA	Organic vapor analyzer
PFD	Process flow diagram
P&ID	Piping and instrumentation diagram
PPM or PPMV	Parts by million or parts by million by volume
PRD	Pressure relief device
TOC	Total organic compound
TVA	Toxic vapor analyzer
VOC	Volatile organic compound
WSPA	Western States Petroleum Association

Glossary

Term	Definition
Accuracy	How close a measurement is to the “true” actual value
ASTM D-86	Standard Test Method for Distillation of Petroleum Products at Atmospheric Pressure
Background	The ambient concentration of total organic compounds determined at least 3 meters (10 feet) upwind from the equipment to be inspected and not influenced by any specific emission point.
Bagging	Encapsulating an area of an equipment component where a leak is located for the purpose of measuring fugitive hydrocarbon emissions using a sampling train.
Confidence Interval	Designates the bounds within which a parameter is expected to lie within a stated degree of confidence
Connector	A flanged, screwed, or other joined fitting used to connect any piping or equipment. This includes sub-components of larger equipment.
Correlation Equation	An equation that relates fugitive hydrocarbon mass emission rates in kilograms/hour, pounds/hour, pounds/day, or pounds/year to instrument screening values in parts per million by volume. Correlation equations are used to calculate emissions from individual instrument screening values.
Default Zero	An average emission rate to be used for components that do not give instrument screening values higher than the background reading.
Duplicate Sample	An independent sample of the same component as another sample but at a different time (for understanding possible temporal variation) or by a different sampling team (for understanding variation by sampling team and/or technique).
Equipment	All components including, but not limited to: valves, pumps, compressors, pressure relief devices, diaphragms, hatches, fittings, sampling ports, pipes, plugs, open-ended lines, gages or sight-glasses.
Error	The amount by which an assumed value deviates from its true value
Gas	Material in gaseous state at operating conditions
Heavy Liquid	Liquids with an ASTM D86 initial boiling point greater than or equal to 150 degrees Celsius (302 degrees Fahrenheit)
I&M	Inspection and Maintenance
LDAR	Leak Detection and Repair
Leak	A screening reading above background. For the pilot refinery, any screening reading of 2.5 ppmv or more above background. For non-pilot refineries, any screening reading of 25 ppmv or more above background.
Light Liquid	Any hydrocarbon liquid that is not a “heavy liquid”; the definition between the two has varied slightly between different programs.
Method 21	EPA Method 21, 40 CFR Part 60 Appendix A-7
Non-Process Lube Oil	Finished lubricants and base oils that require no further processing, other than blending, to produce finished lubricant products, and are at an operating temperature of less than 200 degrees Fahrenheit
Other	Component not classified as a connector, pressure relief device, pump, or valve

Precision	How close two or more measurements are to each other under the same conditions, regardless of whether those measurements are accurate or not. Precision is the measure of the spread of different readings and reflects the reproducibility of a measurement
Pressure Relief Valve	The discharge horn or vent of an automatic pressure-relieving device actuated by the static pressure upstream of the valve and that relieves to atmosphere. Examples:  Pump	The rotating components of a mechanical device using suction or pressure to raise or move liquids. Non-rotating components may be considered connectors. Example: Range	The extent over which an instrument can reliably function within the confines of its specification
Replicate Sample	An independent sample taken as close as possible to the same point in time and space as a primary sample.
Resolution	The smallest discernible change in the parameter of interest that can be registered by a particular instrument.

Screening	monitoring an equipment component for fugitive hydrocarbon emissions using an instrument that measures the concentration of hydrocarbon leaks
Steam-Quenched Pump	A pump that utilizes steam to quench the pump seal.
Valve	The rotating part of any device that regulates the flow or process material by means of an external actuator acting to permit or block passage of liquids or gases. Due to bagging concerns, for the purposes of this study, any valve bonnet flanges will be considered part of the valve.

EXECUTIVE SUMMARY

Petroleum refineries are comprised of thousands of pieces of equipment, piping, and fittings that handle a variety of process streams. This equipment may leak emissions ("fugitive emissions") from gaps in the equipment. Process streams handled by this equipment have historically been categorized by phase, vapor pressure, and/or boiling point as being in either gas, light liquid (initial boiling point equal to or below 302 degrees Fahrenheit), or heavy liquid service (initial boiling point greater than 302 degrees Fahrenheit).

In the Bay Area and more broadly, petroleum refineries are commonly required to monitor equipment in gas or light liquid service for any leaks on a periodic basis and correct any leaks found above a given leak action threshold.

In December 2015, the Bay Area Air Quality Management District's (Air District) Board of Directors approved a revised Regulation 8, Rule 18 (Equipment Leaks) that removed the monitoring exemption for components in heavy liquid service (materials with an initial boiling point greater than 302 degrees Fahrenheit) beginning in January 2018. The Board's adopting resolution directed Air District staff to examine emission reduction and cost effectiveness issues related to the inclusion in Regulation 8, Rule 18 of requirements for monitoring of components in heavy liquid service. This direction required re-evaluating the estimates used for existing emissions from such components as well as well emissions expected to be reduced from such components. Subsequently, as part of a settlement of a legal challenge to the 2015 rule revision, the Air District agreed to: a) complete an ongoing joint study; b) in consultation with affected refineries, produce a report on the results of the study; and c) re-visit the cost effectiveness of monitoring components in heavy liquid service.

This report summarizes the findings of the joint study. The refineries and trade organization that participated in the study have reviewed this report, and their comments have been considered and incorporated as deemed appropriate by the Air District.

The Heavy Liquids Study (or "Study") involved measuring and evaluating emissions from equipment in heavy liquid service at five Bay Area petroleum refineries:

- Chevron Richmond Refinery (Richmond, California),
- Phillips 66 San Francisco Refinery (Rodeo, California),
- Shell Martinez Refinery (Martinez, California),
- Tesoro Golden Eagle Refinery (Martinez, California), and
- Valero Benicia Refinery (Benicia, California).

Two of the five petroleum refineries were subsequently acquired by different entities. The Shell Martinez Refinery is now owned and operated by PBF Energy and is known as the Martinez Refining Company. The Tesoro Golden Eagle Refinery was acquired twice and is now owned and operated by the Marathon Petroleum Corporation and referenced as the Marathon Martinez Refinery.

Study results by petroleum refinery have been blinded in this report.

Four types of equipment were identified for inclusion within the Study: valves, connectors, pump seals, and pressure relief devices that relieve to the atmosphere. The total estimated population of each component type at the five petroleum refineries is shown in the following table.

Table ES-1. Estimated Population of Components in Heavy Liquid Service by Component Type

Component Type	Estimated Population (Start of Study)	Estimated Population (End of Study)
Valves	78,163	52,595
Pumps	2,932	1,075
Connectors	287,700	184,359
Pressure Relief Valves	249	594
Total	**369,044**	**238,623**

The Study involved several phases including study design, preliminary activities, component selection, component screening, mass emissions measurement, laboratory analysis, statistical analysis, and reporting of findings.

Prior to initiating the Study, the Air District, through numerous meetings over the course of a year, discussed and developed the study design with representatives of the five petroleum refineries and their trade association, Western States Petroleum Association ("WSPA").

The Study involved screening selected components in heavy liquids service using a portable screening instrument to measure the concentration of total hydrocarbons from any equipment leaks. From the screened components, a subset had mass emissions measured through physically enclosing the component and drawing a sample of the leak under a vacuum through sorbent tube media that were then sent to an offsite third-party laboratory for analysis.

From the estimated population and using the results of previous studies, a sample size of 2,000 components in heavy liquids service per refinery, 10,000 components in total, were targeted for screening. To begin the Study, 20 components per facility, for a total of 100 samples, were collected and sampled. This number was expanded to address two requests from the petroleum refineries: 1) to sample more components with very low leaks, and 2) to incorporate components associated with storage tanks with materials at ambient temperatures and pressures (to address a concern that Study results may be biased high if only components in process units were included).

Because of the relatively few numbers of pumps and pressure relief devices, it was deemed feasible to include all pump seals and pressure relief devices in heavy liquid service at the five petroleum refineries within the Study.

For connectors and valves, rather than follow a similar methodology for selecting study components that was used in a previous EPA study that developed the existing average emission factors, the five petroleum refineries requested that only connectors and valves within two process units at each petroleum refinery be studied as a practical consideration based on their impact on operations and the additional time that would be required if more process units were studied. Additional process unit(s) at any individual refinery were included in the Study to reach the 2,000-component count to be screened at each facility.

Process units were first selected by the Air District using process flow diagrams provided by each petroleum refinery. After selecting process units, individual process lines were identified by the Air District from petroleum refinery-provided piping and instrumentation diagrams. This selection was done offsite to prevent any bias by the testers related to selection of components via physical examination.

From November 2016 to May 2018, over 10,000 components at the five petroleum refineries were screened. Initially, screening was conducted by personnel from the Air District's Compliance and Enforcement Division who were familiar with both petroleum refinery operation and screening for equipment leaks from components in gas or light liquid service. However, while screening at the second refinery (Refinery B), there was a safety stand down.

Subsequently, due to Air District staff safety concerns, it was decided that each petroleum refinery's fugitive monitoring personnel would screen their own components with a third-party auditor(s) overseeing the process.

Screening personnel followed a protocol that listed the minimum and maximum specifications for screening equipment, calibrations, screening instrument performance tests, and screening technique to follow.

Personnel used standardized field data sheets to record information about each component that was screened including the following:

- Petroleum refinery
- Screening personnel name
- Date and time
- Windspeed / Direction
- Screening instrument serial number
- Process Unit / Area
- Sub-Area
- Component Type
- Component Subtype
- Component Size
- Stream Service
- Component Vibration Amount (None, Low, High)
- Component Cyclic Vibration (Yes, No)
- Elevation
  (Ground, Platform, Top of Vessel / Column, Other)
- Operating Temperature
- Operating Pressure
- Screening Start / Stop Time
- Background Screening Measurement
- Component Screening Maximum Measurement
- Comments

This information was used to identify components to have their mass emissions sampled, as well as to identify components in subsequent analyses.

Sampling of 165 unique components at the five petroleum refineries occurred between January 2017 and November 2018. Each sample included a primary and replicate sample. Additional samples were taken of the background atmosphere within sampled process units as well as several duplicate samples.

The Air District sampled eight components at Refinery A while the remaining were sampled by a third-party contractor hired and managed by WSPA.

The number of components that were screened and sampled by component type is shown in Table ES-2.

Table ES-2. Number of Samples by Component Type

Component Type	Number Screened	Number Sampled	Sampled (%)
Pump Seals	734	32 [1]	4
Connectors	4,710	61	1
Valves	5,349	72	1
Pressure Relief Devices	30	0	0
Total	**10,823**	**165**	**1.5**

Note:

1. Includes one sample of a storage tank agitator seal leak.

Each petroleum refinery is comprised of dozens of process units and process areas that were functionally distinct. Process units were selected for inclusion (meaning sampling was done within these) within the Study with a goal to have a diversity of process unit types.

Table ES-3. Samples Collected in Each Petroleum Refinery Process Unit Type Included in the Heavy Liquids Study

General Process Unit / Area Category	Number of Components Screened	Number of Components Sampled	Sampled (%)
Aromatic Saturation	8	1	13
Asphalt Plant	71	2	3
Blending / Tank Farm	8	2	25
Catalytic Cracking	875	10	1
Catalytic Reformer	2	0	0
Coker	1,450	5	0.3
Crude Unit	1,123	8	1
Crude Unit / Coker	159	2	1
Fuel Gas Treatment	53	0	0
Gas Recovery	22	0	0
Hydrocracker	1,074	38	4
Hydrogen Production	32	0	0
Hydrotreater	4,464	72	2
Hydrotreater and Hydrocracker	834	0	0
Isomerization	1	0	0
Marine Terminal	10	0	0
Other	25	2	8
Polymerization	11	0	0
Reformulation	17	1	6
Separation	9	0	0
Solvent Deasphalting	26	0	0
Sulfur Recovery	114	1	1
Tank Farm	433	21	5
Utilities	2	0	0
Total	10,823	165	1.5

Study Conclusions

The following conclusions may be drawn from the Heavy Liquids Study:

Results:

- Average emission rates at the five petroleum refineries for valves, connectors, and pump seals in heavy liquid service were lower than previously relied upon assumptions.
- Average emission rates were derived for valves, connectors, and pump seals in heavy liquid service as presented in Table ES-4.

Table ES-4. Average Emission Rates by Component Type in the Heavy Liquids Study

Component Type	Previous Emission Factor		Study	
	Emission Factor [(1)] (kg/hour/component)	95% Confidence Interval[(2)] (kg/hour/component)	Emission Factor (kg/hour/component)	90% Confidence Interval (kg/hour/component)
Connectors	2.50E-04	(9.07E-05, 1.13E-03)	9.4E-06	(6.6E-06, 1.60E-05)
Valves	2.30E-04	(9.07E-05, 6.80E-04)	2.84-05	(1.80E-05, 4.43E-05)
Pump Seals	2.10E-02	(8.62E-03, 4.99E-02)	1.18E-04	(4.82E-05, 4.87E-04)

Source:

1. Table IV-1a of CAPOCA in *California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities*, dated February 1999.
2. Table 5-6 of EPA in *Assessment of Atmospheric Emissions from Petroleum Refining: Volume 1. Technical Report,* dated April 1980 (converted to metric units)

- Lighter compounds (C_1 to C_4) were found to comprise only a small portion (less than one percent) of measured emissions although the sample size was limited (emissions from only four components in two process units at one refinery were evaluated).
- Screening values, operating temperature, and operating pressure were found to correlate with measured emissions. However, because of the number of missing operating pressure information for screened components, regression equations were developed using only screening value and temperature.
- Significant differences were found in the responses of screening instruments when screening components in heavy liquid service by process stream material and process stream temperature. Heavier streams typically required longer screening and instrument recovery times for the same component type, subtype, and size.

Issues Uncovered:

- Study design may have impacted results (there is a greater probability of missing large leakers),
- Screening of heavy liquid streams causes screening instruments to drift low (measured screening values are lower than actual),
- Screening pace was faster at Refineries B, C, D, and E, which may have impacted measured screening values (and resulting estimated emissions).

- Study results are dependent upon the petroleum refineries including all components that handle material with an initial boiling point greater than 302 degrees Fahrenheit in the gaseous phase within their leak detection and repair programs.

Recommendations:

- Several improvements (outlined in Section IV.viii **Future Studies**) were identified for future studies including in study design, screening, and sampling techniques.
- Results include emissions from components in heavy liquid service that are currently not in Air District emissions inventories including:
    - components associated with storage tanks and blending areas,
    - components in process units that do not have components in gas or light liquid service, and
    - components in process units that are not currently covered by the existing estimation methodology.

  Because there is no current methodology for estimating the number of such components, methodologies for estimating these components will need to be developed.
- There were several component types for which average emission rates could not be derived either because there were insufficient numbers, their emissions could not be evaluated, or they are recommended for inclusion in a future study:
    - Pressure relief valves that relieve to atmosphere (insufficient numbers)
    - Pump seals with steam or hot oil quenching systems (emissions could not be evaluated)
    - Components handling non-process lube oil (included in a future study).

I. Introduction

This report describes the efforts and results of a study ("Heavy Liquids Study" or "Study") undertaken between the Bay Area Air Quality Management District ("Air District"), five local petroleum refineries (Chevron Richmond Refinery, Phillips 66 San Francisco Refinery, Shell Martinez Refinery, Tesoro Golden Eagle Refinery, and Valero Benicia Refinery), and the Western States Petroleum Association (WSPA) to understand total organic compound emissions from petroleum refinery equipment handling materials with an initial boiling point greater than 302 degrees Fahrenheit. This study was conducted between 2016 and 2021 and included sampling of emissions from equipment leaks at five Bay Area petroleum refineries.

i. Background

Petroleum refinery equipment (pumps, valves, connectors, etc.) leak emissions as "fugitive" emissions through physical gaps in sealing mechanisms and interfaces of components. The material that this equipment serve has historically been categorized as either: 1) gas/vapor, 2) light liquid, or 3) heavy liquid.

The definition of heavy liquid has varied over the years but is based on either: 1) the initial boiling point, 2) the temperature at which 10 percent evaporates after reaching the initial boiling point, or 3) the vapor pressure of the material or components that comprise a significant percentage of the material.

There have been several studies of fugitive emissions from petroleum refinery equipment. In the late 1970s, the United States Environmental Protection Agency (EPA) initiated the Petroleum Refinery Assessment Study, and equipment leak data from 13 petroleum refineries was collected. In this study, equipment was screened using portable analyzers that measured total organic compound leak concentrations on a parts per million by volume (ppmv) basis and a fraction of the screened components had mass emissions sampled through bagging of selected components. Average emission factors and correlations for each equipment type were developed based on the screening and bagging data collected in this study. The results of this study (called the 1980 Refinery Study or 1980 EPA Study in this report) were published in 1980 ("EPA 1980 Report").

From this study, EPA developed three methods for estimating fugitive emissions from components based upon whether a component was routinely monitored as part of an inspection and maintenance (I&M) program, now commonly referred to as a leak detection and repair (LDAR) program. In an I&M or LDAR program, components are periodically monitored for leaks and any component discovered leaking above a leak threshold is repaired or replaced.

EPA developed three methods for estimating fugitive emissions from equipment leaks:

1) average emission factors (where no monitoring is done),
2) screening range emission factors (where leak/no leak monitoring is done), and
3) Correlation Equations (where monitoring of individual leak concentrations is done).

For components that are not monitored as part of an LDAR program, EPA developed average emission factors that varied based on the component type (e.g., pump seals, valves, connectors) and stream service (gas/vapor, light liquid, heavy liquid). When using this method, emissions are estimated by multiplying the number of components in a given stream service by a corresponding average emission factor and the number of hours within a year that each component was in service.

For components that are monitored as part of an LDAR program but where individual leak concentrations are not recorded but only whether a component is leaking above or below a leak threshold, EPA developed separate average emission factors for components leaking below and above the threshold. These factors also varied by component type and stream service.

Where leak concentration measurements are recorded as part of an LDAR program, EPA developed regression equations that correlated leak concentrations to mass emissions by component type.

These three methods of estimating emissions are shown in the following table.

Table I-1. Methods for Estimating Fugitive Emissions

Method	Description	LDAR Monitoring
Method 1	Average Emission Factors	No monitoring
Method 2	Screening Data	"Leak/No Leak" monitoring
Method 3	Correlation Equations	Individual monitor readings

In 1993, the Western States Petroleum Association (WSPA) and the American Petroleum Institute (API) conducted a joint study ("1993 Refinery Study") to develop new emission correlation equations for refineries using Method 3 to estimate fugitive emissions.

Samples were collected from five refineries: two located in southern California, two in northern California, and one in Pennsylvania. All five refineries had I&M programs to reduce the number of leaking components. Sampling was conducted over approximately a six-month period by two separate sampling teams. Approximately 270 components were sampled at the five refineries. The study sampled the following component types: valves, pumps, connectors, and open-ended lines.

EPA updated a 1993 "Protocol for Equipment Leak Emission Estimates" to present standard procedures for estimating mass emissions from equipment leaks and included the average emission factors from the 1980 study as well as revised correlation equations, default zero emission rates, and pegged emission rates from the 1993 WSPA/API study. The results were published in a 1995 report ("EPA 1995 Report").

In 1996, API published (API Publication Number 337 *Development of Emission Factors for Leaks in Refinery Components in Heavy Liquid Service*), the results of a study to develop new average emission factors for components in heavy liquid service. Existing LDAR screening data from four refineries in Southern California were combined with new screening data from two Washington state refineries.

The screening results were combined with Method 3 correlation equations, as listed in the 1995 EPA Protocol, to derive average emission factors for components in heavy liquid service.

Two of the Southern California refineries included heavy liquid service components into their LDAR program. The other two refineries conducted heavy liquid service screening as part of a planning effort for the 1993 WSPA/API study.

The California Air Pollution Control Officers Association (CAPCOA), with input from six air districts and the California Air Resources Board (CARB), reviewed the EPA 1995 Report and developed guidelines for estimating mass emissions from fugitive leaks. These guidelines were published in *California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities*, dated February 1999.

The guidelines listed four methods for estimating emissions from equipment leaks:

Table I-2. CAPCOA Guidelines Methods for Estimating Fugitive Emissions

Method	Description	LDAR Monitoring
Method 1	Average Emission Factors	No monitoring
Method 2	Screening Data	"Leak/No Leak" monitoring
Method 3	Correlation Equations	Individual monitor readings
Method 4	Unit-Specific Correlation Equations	Individual monitor readings

The guidelines incorporated the 1980 EPA Refinery Study emission factors for Method 1 and Method 2 and the 1993 WSPA/API data with some revisions for Method 3. Method 4 is a process for determining process unit-specific correlation equations.

In addition, CAPCOA surveyed California air districts for which components are excluded from regulatory-required Inspection and Maintenance (I&M or LDAR) programs and created an exclusion list for those components from components counts when using the Correlation Equations (Method 3) since those components would not be monitored. By default, those components would be required to use average emission factors (Method 1).

Because the published average emission factors are on a per component basis, when using Method 1 (Average Emission Factors) to estimate emissions, an inventory of the different component types by stream service is required. However, as components are routinely added, removed, and replaced for maintenance or modification purposes, petroleum refineries typically do not maintain an inventory of components unless required to do as part of an LDAR program. The petroleum refineries within the Air District have an inventory of components in gas and light liquid service but, except for one petroleum refinery, do not have an inventory of heavy liquid service components.

To estimate emissions from components in heavy liquid service using average emission factors, the number of such components are estimated using U.S. EPA published component counts by process unit for a model refinery. However, when comparing the actual inventories of components in gas and light liquid service with those published for a model refinery, the model refinery counts were found to be significantly lower than actual. Therefore, rather than using the proposed counts, multipliers representing the number of components in heavy liquid service to the number of components in gas and light liquid service for a given process unit were derived from the published count. These multipliers in conjunction with the actual inventory of components in gas and light liquid service are used to estimate the number of components in heavy liquid service at a petroleum refinery where an actual inventory is unknown. However, this method for estimating heavy liquid service components does not account for process units that are not listed in the EPA document as well as process units that may only have components in heavy liquid service. For example, storage tank farms are not included in EPA's table of process units. Therefore, the number of components in heavy liquid service that are associated with storage tanks have not historically been estimated and emissions from these components have not been included in any emissions inventory.

In 2013, the Air District determined that the petroleum refineries were not reporting previously reported emissions from non-monitored components handling heavy liquid streams within annual emissions inventory updates. Since these components were not monitored within a leak inspection program, the petroleum refineries were required to estimate and report these emissions using the Method 1 average emission factors from the 1999 CAPCOA Guidelines. In late 2014 and early 2015, the petroleum refineries and the Western States Petroleum Association began discussions with the Air District regarding the use of these average emission factors and how best to obtain representative data to use as a substitute.

The Air District's Regulation 8 (*Organic Compounds*), Rule 18 (*Equipment Leaks*) limits emissions of total organic compounds from equipment leaks at petroleum refineries, chemical plants, bulk plants, and bulk terminals. Regulation 8, Rule 18 includes emissions standards, inspection, monitoring, and recordkeeping requirements.

Regulation 8, Rule 18 limits the maximum allowable concentration (parts per million by volume, ppmv) of equipment leaks before a leak is required to be minimized and then repaired within a given time allowance that is based on who discovers the leak (the Air District or the facility). Unless exempted, each piece of equipment is required to have a unique identifier and required to be monitored within an LDAR program.

Regulation 8, Rule 18 does not include a definition for heavy liquid service. Rather, the rule had a limited exemption for components handling organic liquids having an initial boiling point greater than 302 degrees Fahrenheit. Equipment that met this criterion were subject to emission standards but exempted from monitoring requirements.

In December 2015, the Air District's Board of Directors approved a revised Regulation 8, Rule 18 that removed the monitoring exemption for components in heavy liquid service beginning in January 2018.

As a basis for determining that monitoring of components in heavy liquid service is cost effective for the rule amendment, the Air District relied upon the existing average emission factors for components in heavy liquid service that were published in the EPA 1980 Report and carried forward in the EPA 1995 Report and the 1999 CAPCOA Guidelines.

Since the average emission factors were developed, there have been significant advances in component design and sealing mechanisms, principally to meet increasingly stringent leak standards for components handling gas and light liquid streams. In addition, industry standards and regulatory requirements improved upon the audio-visual-olfactory (AVO) inspections of component handling heavy liquid streams and thus, significant leaks are more likely to be found. WSPA and the local petroleum refineries posited that because of these advancements, the existing average emission factors likely do not represent the average emission rates of components at the five Bay Area refineries.

The Air District's Board of Directors considered these arguments and along with the revised rule, the Board passed a resolution requiring the Air District to conduct a joint study with the petroleum refineries to measure mass emissions from components in heavy liquid service and re-visit the cost effectiveness determination made with the revised rule.

As such, a new sampling study was required.

ii. Study Objectives

The principal objective of the Study was to answer the following:

- What are the average emission rates for Bay Area petroleum refinery components in heavy liquid service?

The results of this objective will be used by the Air District to address the questions by the Air District's Board of Directors' resolution in a separate report ("Regulation 8, Rule 18 Staff Report").

In addition, the Air District analyzed data collected from the study to answer the following questions:

- Are there significant differences in emission rates for components in different heavy liquid streams?
- Are there significant differences when monitoring components handling heavy liquid streams as compared to gas/vapor or light liquid streams?
- What, if any, correlations exist between component classifications and leak rates and/or emission rates?
- Which factors have a statistically significant impact on emission rates from components in heavy liquid service?
- Can data generated from the current study be combined with data from other sources/previous studies?

The following questions were also expected to be addressed by the Study:

- Can confidence intervals (accounting for emissions rate variability, population uncertainty, and systemic and random errors in experimental design, sampling, chemical analysis, and statistical analysis) be constructed for each computed emission factor?
- Were there any errors introduced during selection, sampling, or processing of collected data that may affect the internal or external validity of study results?

iii. Historical Perspectives

There have been multiple studies, reports, and other documents developed by agencies and industry over the past 70 years pertaining to fugitive emissions from petroleum refinery equipment.

This section identifies and discusses studies germane to the current effort but is not intended to be an exhaustive listing of all petroleum refinery fugitive emissions related studies.

Several studies and documents have been identified through references in others, but copies of these primary documents could not be located for review. In some places, the results of these studies were discussed and presented in secondary documents, which were used as reference material. Where neither primary documents nor references could be found, it is believed the work discussed in those documents has been superseded by subsequent efforts.

I.iii.1. Joint District, Federal and State Project for the Evaluation of Refinery Emissions

In September 1955, a multiple agency study ("Los Angeles County Joint Project") was initiated and carried out over a three-year period to understand emissions from petroleum refineries in Los Angeles County.

The agencies and organization involved in the study included:

- Los Angeles County Air Pollution Control District (predecessor to South Coast Air Quality Management District)
- U.S. Department of Health, Education, and Welfare, Public Health Service, Air Pollution Engineering Research,
- State of California, Department of Public Health, Bureau of Air Sanitation (predecessor to California Air Resources Board), and
- Western Oil and Gas Association (predecessor to Western States Petroleum Association), Air Pollution Control Committee.

This study evaluated emissions from various petroleum refinery source categories including:

- storage tanks,
- catalyst regeneration units,
- pipeline valves and flanges,
- pressure relief valves,
- pumps and compressors,
- compressor engines,
- cooling towers,
- loading facilities,
- wastewater separators and process drains,
- turnarounds, equipment maintenance, and blowdown systems
- waste gas flares,
- pipeline blind changing,
- boilers and process heaters,
- vacuum jets, and
- air blowing operations (air blown through petroleum products, agitation during treating, asphalt processing).

Results were published in nine reports (collectively titled "*Joint District, Federal and State Project for the Evaluation of Refinery Emissions*"):

1. Kanter, C.V., et al., "Interim Progress Report". July 1956.
2. Palmer, R.K., "Hydrocarbon Losses from Valves and Flanges". Report No. 2. March 1957.
3. Steigerwald, B.J., "Hydrocarbon Leakage from Pressure Relief Valves". Report No. 3. May 1957.
4. Sussman, V.H., "Atmospheric Emissions from Catalytic Cracking Unit Regenerator Stacks". Report No. 4. June 1957.
5. Bonamassa, F., "Emissions of Hydrocarbons to the Atmosphere from Cooling Towers". Report No. 5. August 1957.

6. Steigerwald, B.J., “Emissions of Hydrocarbons from Seals on Pumps and Compressors”. Report No. 6. December 1957.
7. DeVorkin, H., Steigerwald, B.J., “Emissions to the Atmosphere from Boilers and Process Heaters”. Report No. 7. May 1958.
8. Kanter, C.V., et al., “Emissions to the Atmosphere from Eight Miscellaneous Sources in Oil Refineries”. Report No. 8. June 1958.
9. Kanter, C.V., et al., “Emissions of Air Contaminants from Oil Refineries”. Final Report. June 1958.

Copies of the above reports could not be located for review. However, the results of these reports were discussed and referenced within a document (Public Health Service 1960) that was published two years after these reports as well as in subsequent reports including EPA 1976.

Table I-3. *Fugitive Components Surveyed in Los Angeles County Joint Project*

Component Type	Refineries Surveyed	Component Population	Components Surveyed
Valves	11	132,000 (1)	~ 10,000 (2)
Flanges	Unknown	Unknown	326 (1)
Pressure Relief Valves (to atmosphere)	7 (4)	1,465 (vapor systems) (3) 690 liquid lines)	> 400 (1) (vapor systems)

The results of this study were the basis for most emission factors listed in the "petroleum refinery" section of the first edition of U.S. EPA's AP-42 Compilation of Air Pollutant Emission Factors.

I.iii.2. 1970s Studies

In the 1970s, multiple studies were undertaken by industry and various agencies to understand volatile organic compound emissions from equipment leaks. EPA contracted with a third-party to evaluate and revise petroleum refinery emission factors in a large-scale study over a three-year period with results published in 1980. This work is discussed in the next section (**1980 EPA Study**).

In 1976 to 1977, the California Air Resources Board contracted with KVB Engineering to conduct a study (KVB Study) in the South Coast Air Basin like the Los Angeles County Joint Project. However, there was less testing at petroleum refineries. Fugitive organic emissions (emission rate and composition) from petroleum refinery valves, pumps, separators, and cooling towers were measured.

Study results were published in “Control of Hydrocarbon Emissions from Stationary Sources in the California South Coast Air Basin”, Final Report Volumes I and II, KVB, Inc., 1978. A copy of this publication could not be located. However, the author, Hal Taback, presented a summary of the findings in a presentation titled “Petroleum Refinery Fugitive Emissions Measurement Emission Factors and Profiles” that was published in EPA “Proceedings: Symposium/Workshop on Petroleum Refining Emissions”, April 1978.

The study occurred over one week at a small (40,000 barrels per day) asphalt refinery and two weeks at a large (180,000 barrels per day) petroleum refinery. Valves and flanges were sprayed with a soapy solution to detect leaks and then any found leaks were classified as either “small”, “medium”, or “large” based upon the rate of bubble formation. The method for measured emission was dependent upon the leak classification. Components with large leaks were enclosed in a polyethylene bag with gas allowed to escape through tubing to a gas meter, sample bottle and total hydrocarbon analyzer. Small and medium leaks, a dilution method was used. Filtered (using activated charcoal and silica gel) ambient air was metered into the polyethylene bag and a sampling pump connected to the sampling tube drew a steady sample stream. After reaching steady state (determined by an attached hydrocarbon analyzer), the leak rate was the product of measured air flow and measured hydrocarbon concentration.

The KVB Study found leaks varied by component subtype (Table I-6) as well as stream material and component size (Table I-7).

Table I-6. KVB Study Results by Component Type

Component Type	Number Tested (1)	Leaks Measured	Leakers Identified (1)		
			Small	Medium	Large
Valves (All)	5,800	25	157	62	33

For pump seals, the KVB Study identified leaks using a Bacharach Threshold Limit Value (TLV) total hydrocarbon analyzer and then measured emissions similarly to valves and flanges for any found leaks. The study found differences in results between the types of pump seals. Although both mechanical and packed seal pumps had similar leak frequency (approximately 50 percent), mechanical seals had much lower (one-sixth) emissions than packed seal for gas service (a Reid Vapor Pressure of greater than 26 psi) than for liquid service pumps where emissions for both mechanical and packed seal pumps were nearly the same.

Table I-8. KVB Study Large Refinery Results by Pump Seal Type and Reid Vapor Pressure

Pump Seal Type	Reid Vapor Pressure (psi)	Number Tested (1)	Leakers Identified (1)			Emission Factor (1) (lb/day/seal)
			Small	Medium	Large	
Mechanical	> 26	19	8	0	2	7

	< 26	12	5	0	1	0.4
	Total	16	5	0	2	N/A

Notes:
1. Source: Table 6 of EPA Proceedings 1978.

The KVB Study concluded that the emission factors for valves, flanges, and pumps in AP-42 that were based on the 1957 Los Angeles County Joint Study were reasonable.

The KVB Study found valves and flanges leaked less often as found in the Los Angeles Joint Project but with greater magnitude of emissions. Because of this disparity and the limited refinery sample size, CARB initiated its own study. The results of this study were published in a CARB Publication titled “Control of Emissions from Leaking Valves and Flanges at Oil Refineries” by J.J. Morgester (CARB Chief of Enforcement) and others, dated November 15, 1978. A copy of this publication could not be located for review. However, the authors of the publication summarized the study within a 1979 journal article (Chemical Engineering Progress 1979) that was available for review.

For nine days in February 1978, CARB staff inspected valves and flanges in 49 process units at six Los Angeles area refineries. Because of time constraints, only valve-associated flanges were inspected. Components were visually inspected for liquid leaks as well as sprayed with a soapy solution for detecting gaseous leaks. Any identified gaseous leaks were characterized as either a “slow” or “fast” leak based on either the number of drops per minute (for liquid leaks) or the rate and size of soap bubble formation (for gaseous leaks). To measure emissions, any liquid leaks were collected in graduated cylinders and quantified. Components with gaseous leaks were enclosed in a polyethylene plastic bag and had tubing attached to the bag and to a pressure gauge and dry gas volume meter. After waiting until leakage in the bag reached steady state, the gas leakage flow rate at standard conditions was calculated. A gas sample was taken in a Mylar bag and analyzed for methane and non-methane hydrocarbon content.

Table I-9. Summary of 1978 CARB Study at Six Los Angeles Area Petroleum Refineries

Process Unit	Number of Units Inspected [1]	Valves [2]			Flanges [2]

In the late 1970s, the Bay Area Technical Subcommittee of the Western Oil and Gas Association contracted with the Radian Corporation to evaluate fugitive emissions at six San Francisco Bay Area petroleum refineries. In addition to the current five petroleum refineries, a sixth petroleum refinery, Pacific Refining Company, was operating in Hercules, California. Pacific Refinery, which began operation in 1966, ceased operations in 1995. The results of this study were published in a document titled "Valve Screening Study at Six San Francisco Bay Area Petroleum Refineries", Radian Report DCN 79-219-370-03, dated January 24, 1979. A copy of this document could not be located for review.

I.iii.3. 1980 EPA Study

In 1977, the U.S. EPA's Office of Air Quality Planning and Standards, through a contractor (Radian Corporation), reviewed and adjusted emission factors for petroleum refinery source categories within EPA's AP-42 document. Source categories were prioritized for future emissions evaluation and a testing strategy was developed for source categories given a high priority. The results of this effort were documented in EPA's 1977 *Revision of Emission Factors for Petroleum Refining* (EPA 1977).

The fugitive source category was one of four categories that were recommended as a high priority for an emissions testing program. As a rationale for testing, the report identified several emissions dependent parameters (equipment type, equipment age, housekeeping practices, and frequency of maintenance) as having changed since fugitive emission factors were developed from the Los Angeles County Joint Project. However, the document stated that "improved fugitive emission factors may still have an error of ± 50% to ± 75%" (page 39 of EPA 1977). Fugitives were assigned a high priority as "they represent the second largest source of refinery emissions and the source with the greatest potential for emission factor development." (Page 44 of EPA 1977)

As a result of this recommendation, a three-year refinery assessment program was initiated and carried out between 1977 and 1980 by Radian Corporation under an EPA contract. This program collected and evaluated emissions at 13 petroleum refineries located throughout the United States from multiple refinery source categories including from fugitive sources. One of the objectives of the program was the "quantification of fugitive hydrocarbon emissions from petroleum refineries".

Petroleum refineries were selected based on age and size (larger or smaller than 50,000 barrels per day of crude oil capacity) in one of four geographical areas: East Coast, Gulf Coast, West Coast, and Middle United States (Midwest and Mid-Continent). Because of the complexity and difficulty of doing otherwise, the age of the oldest refinery operating unit was used for selection. Petroleum refineries where the oldest refinery operating unit was more than 20 years old were defined as old while refineries that had no operating unit older than 20 years old were classified as new. Using this categorization, eight old / large, four old / small, and one new / large petroleum refineries were identified for inclusion within the study.

For the fugitive source category, components at nine petroleum refineries were studied.

As operating temperature and operating pressure were anticipated to significantly impact fugitive emissions from a component, process units were categorized as high or low pressure (above or below 150 psig) and high or low temperature (above or below 100 degrees Celsius). This classification was based on the major process unit equipment (such as a reactor) as this information was not identified for each piece of equipment.

Process unites were distributed equally among the categorizations, but the choice of process units "was made on an individual refinery basis, with as much diversity among units sampled as the differences among refineries allowed." (Page 5 of EPA 1980 Volume 2 Appendix A)

At each refinery, six to nine refinery process units were selected (see Table I-10).

Table I-10. Number of Process Units Sampled in 1980 EPA Study

Refinery Process Unit	Number of Sampled Units [1]
Atmospheric Distillation	7
Vacuum Distillation	4
Thermal Operations (Coking)	2
Catalytic Cracking	5
Catalytic Reforming	6
Catalytic Hydrocracking	2
Catalytic Hydrorefining	2
Catalytic Hydrotreating	7
Alkylation	6
Aromatics / Isomerization	3
Lube Oil Manufacture	2
Asphalt Manufacture	1
Fuel Gas / Light Ends Processing	11
LPG	2
Sulfur Recovery	1
Other	3

Note:
1. Table 3-1 of EPA 1979.

Choice parameters (those variables which directly impact emissions) and correlating parameters (additional variables that have a secondary impact on emissions) were identified. However, only choice parameters were used for selecting specific components in a statistical experimental design (fractional factorial experimental design).

Table I-11. Choice Variables and Variable Ranges by Component Types in 1980 EPA Study

Component Type [1]	Choice Variable	Variable Ranges Found for Screened Sources
Valves	Pressure	-10 to 3,000 psig
	Temperature	100 to 925 °F
	Fluid State	Gas, Liquid, Two-Phase
	Service	In-Line, Open-ended
	Function	Block, Throttling, Control
	Size	0.5 to 36 inches
Flanges	Pressure	-14 to 3,000 psig
	Temperature	-30 to 950°F
	Fluid State	Gas, Liquid, Two-Phase
	Service	Pipe, Exchanger, Vessel, Orifice
	Size	1 to 54 inches
Pump Seals	Pressure	0 to 3,000 psig
	Temperature	0 to 800°F
	Capacity	0 to 100,000 gallons per minute
	Shaft Motion	Centrifugal, Reciprocating
	Seal Type	Mechanical Seal, Packed Seal
	Liquid Reid Vapor Pressure (RVP)	Complete range
Pressure Relief Valves	Pressure	0 to 1,350 psig
	Temperature	40 to 1,100 °F
	Fluid	Gas, Liquid

Notes:

1. Only component types included in the Heavy Liquids Study are shown here.
2. Source: Table 4-1, 1980 U.S. EPA Volume 1

After identifying choice parameters, a test plan was created that specified the number of components with various variable configurations (e.g., four control valves in gas service that 4 to 8 inches in size in a reforming process unit) for inclusion within the study.

Other than process drains, specific components within each test category were randomly selected from petroleum refinery drawings (piping and instrumentation diagrams and process flow diagrams) and given a unique identification number. This method removed potential bias from selecting in the field (preventing selection of components visually leaking or not) as well ensured that the designated number of components were distributed in as wide a range of process variables.

Each of the pre-selected individual components were physically located in the field and affixed with physical tags with the assigned unique identification number. When components could not be located or were physically inaccessible, alternate components were selected from refinery drawings.

Selected components at each refinery were first "screened" for leaks using portable hydrocarbon detectors that measured the concentration of hydrocarbons being emitted at a leak location. Components found leaking at 200 parts per million by volume (ppmv) or greater were candidates to have mass emissions sampled.

Components were screened using a Bacharach Instrument Company J-W Model Threshold Limit Value Sniffer (TLV Sniffer), a catalytic combustion detector, calibrated with hexane and using component type-dependent established screening procedures. The instrument probe was held as close as possible to the location of a potential leak to increase screening reading reproducibility and reduce potential wind effects.

A second instrument, Century Instrument Company Organic Vapor Analyzer (OVA) Model OVA-108, was also used. However, because the OVA instrument employs a flame ionization detector rather than catalytic combustion detector, components identified with this instrument were re-screened with the TLV Sniffer prior to sampling for consistency purposes.

For valves, both the valve stem and packing gland were screened by placing the instrument probe at the interface (0 centimeters from surface) and held at the location for a minimum of five seconds after which the detector reading was recorded. This was repeated at three other points that were 90 degrees apart. The maximum of the eight readings was compared against the sampling criterion. In addition, a wire extension guide was used to obtain two additional measurements, one for the valve stem and one for packing gland, at five centimeters from the surface.

For flanges, the probe was placed at 2-inch intervals all around and right against the outside perimeter of the flange interface and held for a minimum of five seconds and the detector reading recorded. The maximum of all readings was used with the sampling criterion.

For pressure relief valves, only those that vented to atmosphere were screened. Those that did not vent to atmosphere were considered flanges as they could only leak to the atmosphere at the connecting flanges. The instrument probe was placed at two-inch intervals around the perimeter of the vent as well as the center of relief vent exit (“horn”), held for a minimum of five seconds, and the instrument reading recorded. If the top of the horn could not be accessed, the relief valve weep hole (located near the bottom of the horn) was screened.

Pump seals were screened similarly as valves where the instrument probe was placed as close as possible to interface of the pump shaft and pump housing and four readings at 90 degrees apart from each other recorded. The maximum reading was used with the sampling criterion. Some larger pumps were found to have two seals (inboard and outboard) and each seal was screened separately.

Emissions rates from components that had leaks with screening values below 200 ppmv hydrocarbon were considered negligible. Therefore, only components with leaks that had screening values greater than 200 ppmv hydrocarbon were candidates for sampling.

Several modifications to the experimental design were made as the study progressed. Because components in gas and light liquid service were found to leak at a greater frequency and magnitude, a higher proportion of valves and pump seals in gas and light liquid service were sampled. The number of sampled flanges was also reduced due to low leak frequency and emissions magnitude found from earlier study stages.

Components selected for sampling were enclosed in 1.5 to 5 mil Mylar sheeting, forming a “tent” or “bag”, fitted with bulkhead fittings, and had Teflon tubing connected where enclosed emissions were pulled through a cold trap (to condense any water vapors), a dry gas meter, and a vacuum pump (see Figure I.1). A small diaphragm pump connected after the dry gas meter pulled a slip steam into a sample bag. The tent was kept under a vacuum – monitored by a magnehelic gauge connected to a separate line – to ensure that emissions did not escape.

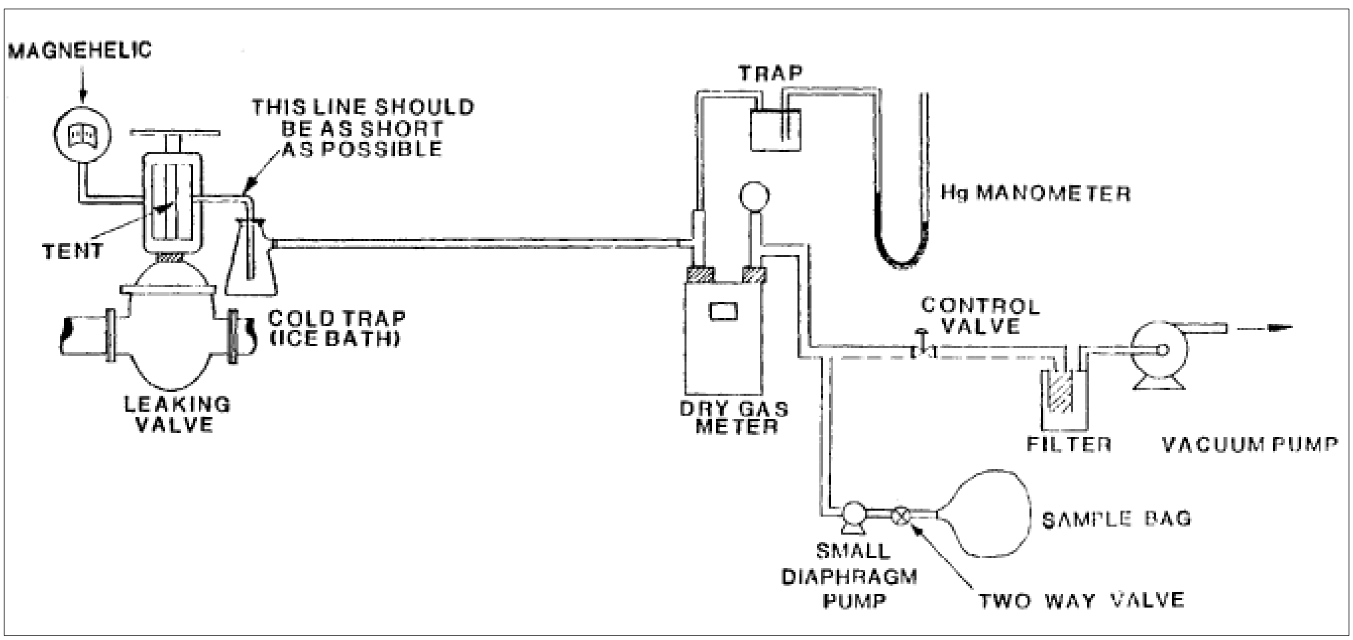

***Figure I.1**. Sampling Train for 1980 EPA Study*

(Source: Figure 4-1, p. 70 of EPA 1980 Volume 1)

Mylar was used for its high melting point, toughness, and ability not to significantly adsorb hydrocarbons.

Sampling occurred after the vacuum pump created a vacuum and once the tent enclosed space reached equilibrium, determined by measuring the hydrocarbon concentration exiting the sampling train with a TLV Sniffer. After flushing the sample bag with sample gas, between five to seven liters of sample gas was captured. In addition, a sample of the ambient air near the tent was captured via a plastic syringe and injected into a separate sample bag. The two sample bags (component sample and ambient air sample) as well as the sealed cold trap (for organic condensate analysis) were sent to and analyzed at an onsite mobile laboratory.

In the case of large leaks, the sampling train in Figure I.1 was altered where the vacuum pump was disconnected, and sample gas allowed to exit after the dry gas meter.

The number of components that were screened and sampled by stream service is shown in Table I-12.

Table I-12. Number of Components Screened and Sampled in 1980 EPA Study

Component Type [1]	Stream Service	Number of Components	
		Screened [2]	Sampled [3]
Valves	Gas / Vapor	563	154
	Light Liquid / Two-Phase	913	330
	Heavy Liquid	485	32
Flanges	All	2,094	62
Pump Seals	Light Liquid	470	296
	Heavy Liquid	292	66
Pressure Relief Valves	Gas [4]	148	58

2. Source: Table 5-3 of EPA 1980 Volume 1

It was not possible to sample all candidate components (those that that had screening values greater than 200 ppmv) because of equipment and time constraints. Therefore, a sampling strategy was employed.

As not all candidate components were sampled, emissions from non-sampled components had to be estimated. Because results from sampled components displayed a similar skewness as screening results, a correlation between the two was identified.

Least square regression analyses were done for each component type using the logarithm of the screening value and logarithm of the sampled emissions rate.

Different sets of equations were established using screening values originally measured during field screening as well as those measured before sampling and the equation that had the highest correlation coefficient was used to estimate emissions from non-sampled components. For valves, pump seals, and relief valves; the screening values measured before sampling resulted in the highest correlation (correlation coefficients of 0.78, 0.68, and 0.78) while for flanges, the original screening value resulted in the highest correlation (correlation coefficient of 0.74).

These equations were used to estimate emissions from non-sampled components that had screening values greater than 200 ppmv and components with screening values less than 200 ppmv were assumed to have negligible (zero) emissions.

Using a mixed lognormal model and accounting for systematic errors, emission factors by component type and stream service were developed (Table I-14).

Table I-14. Estimated Non-Methane Hydrocarbon Emissions from Fugitive Components from 1980 EPA Study

Component Type	Stream Service	Emission Factor Estimate (2) (lb/hour/component)
Valves	Gas / Vapor	0.059
	Light Liquid / Two-Phase	0.024
	Heavy Liquid	0.0005
Flanges	All	0.00056
Pump Seals	Light Liquid	0.25
	Heavy Liquid	0.046
Pressure Relief Valves	Gas	0.19

Notes:
1. Per Table 5-6 of EPA 1980 Volume 1

I.iii.4. 1993 Refinery Study and 1995 EPA Protocol

In 1993, the Western States Petroleum Association and the American Petroleum Institute (API) initiated and carried out a study (1993 Refinery Study) to develop new correlation equations for estimating emissions from hydrocarbon leak concentration measurements. These equations were compared to those found during the 1980 EPA Study. Emissions data was collected by Radian Corporation personnel from five petroleum refineries (two in northern California, two in southern California, one in Pennsylvania). Each refinery had an inspection and maintenance program for identifying and correcting leaks.

A Regulatory Advisory Committee comprised of the U.S. EPA, CARB, Air District, and the South Coast Air Quality Management District provided input on planning, auditing, and results review. In addition, Air District and SCAQMD staff performed side-by-side screening (at Air District and SCAQMD refineries, respectively) with Radian personnel for comparisons of screening results. The U.S EPA contracted with an auditor, Research Triangle Institute, performed duplicate sampling as well as testing at four refineries.

The 1993 Refinery Study produced revised correlation equations as well average emission factors for components found leaking at background concentrations (called “default zeros”) as well as components leaking at concentrations greater than instrument spans (either 10,000 ppmv or 100,000 ppmv if a dilution probe were used) called “pegged factors”. The use of these equations, default zeros, and pegged factors was contingent upon component screening. The study did not attempt to revise average emission factors for where routine component screening was not being done.

These results were published in two API documents (API Publication 4612 and API Publication 4613) as well as incorporated by the EPA into a document (U.S. EPA 1995 EPA Protocol for Equipment Leak Emission Estimates. November 1995. EPA-453/R-95-017, “1995 EPA Protocol”) that outlined the methodologies for estimating emissions from equipment leaks.

The 1995 EPA Protocol combined data from the 1993 Refinery Study and additional studies conducted at marketing terminals (1993 Marketing Terminals Study), oil and gas production sites (1993/1995 Oil and Gas Production Study) and synthetic organic chemical manufacturing industry (SOCMI) to provide established procedures and methodologies for estimating fugitive hydrocarbon emissions.

The average emission factors from the 1980 EPA Study were incorporated into the 1995 EPA Protocol.

I.iii.5. API Publication Number 332

Depending upon the regulatory requirement, components may be required to be screened for equipment leaks either at the surface or at up to one centimeter from the surface. The screening distance may also vary based on the access to the surface, potential for instrument contamination (presence of water on the component surface), or potential safety hazard (such as the presence of rotating parts). Typically, the choice of screening instrument is left to the facility.

However, the component leak screening value recorded by a screening instrument may be affected by both the monitoring distance and the screening instrument used. To understand these differences, WSPA and the American Petroleum Association conducted a study to develop correlation equations between fugitive hydrocarbon screening instruments that were commonly in use at the time. The study investigated four different screening instruments:

- Foxboro OVA 108,
- Bacharach Threshold Limit Value Sniffer (TLV Sniffer®),
- HNU® PI-101, and
- Foxboro Total Vapor Analyzer (TVA) 1000, both flame ionization detector (FID) and photo ionization detector (PID).

The study collected equipment leak screening data from a southern California refinery over one week in December 1993 and from a northern California over one week in January 1994. It is not stated but it is believed that the southern California refinery was in the South Coast Air Quality Management District while the northern California refinery was in the Air District.

The study identified there to be approximately 400,000 valves and connectors between the two refineries and chose 271 components for the intercomparison of screening instrument performance. Most components were identified by each petroleum refinery and the rest by study field staff.

However, not all 271 components were screened with all four instruments (due to instrument difficulties) although all were screened by the OVA-108.

The study concluded there to be differences between measured component leak screening values based on screening instrument and screening distance and developed correlation equations (see Table I-15) to convert screening values at different screening distances between instruments.

Table I-15. API Publication 332 Equations Relating Screening Values from Different Instruments

Screening Instruments	Screening Distance	Number of Data Pairs	Correlation Equation (2)	Correlation Coefficient
OVA versus TLV Sniffer ®	At Surface	174	OVA@ = $(6.09 \times 10^{-1}) \times (TLV@)^{1.216}$	0.85
	1 centimeter	164	OVA1 = $(4.58 \times 10^{-1}) \times (TLV1)^{1.222}$	0.75
OVA versus TVA FID	At Surface	54	OVA@ = $(1.54) \times (TVAF@)^{0.935}$	0.90
	1 centimeter	52	OVA1 = $(1.02) \times (TVAF1)^{1.013}$	0.83

Notes:
1. Source: Table ES-1, API Publication Number 332 (August 1995). *Comparison of Screening Values from Selected Hydrocarbon Screening Instruments.*
2. OVA@ = OVA screening value at the surface of a component
   OVA1 = OVA screening value at 1 centimeter from the surface of a component
   TLV@ = TLV Sniffer ® screening value at the surface of a component
   TLV1 = TLV Sniffer ® screening value at 1 centimeter from the surface of a component
   TVAF@ = TVA screening value at the surface of a component
   TVAF1 = TVA screening value obtained at 1 centimeter from the surface of a component

In addition, the study developed an adjustment factor for adjusting OVA screening values taken at 1 centimeter from the surface of a component to OVA screening values taken at the surface.

$$OVA@ = (3.60) \times (OVA1)^{0.962} \qquad [I\text{-}1]$$

where:
OVA@ = OVA screening value at the component surface
OVA1 = OVA screening value at 1 centimeter from the surface

From an inspection of Equation I-1, screening at the surface would result in screening value measurements that are 2.5 to 3.6 times greater (depending upon the screening value) than when measuring at one centimeter from the surface.

The variation in screening measurements that are represented in Equation I-1 is shown in Figure I.2 .

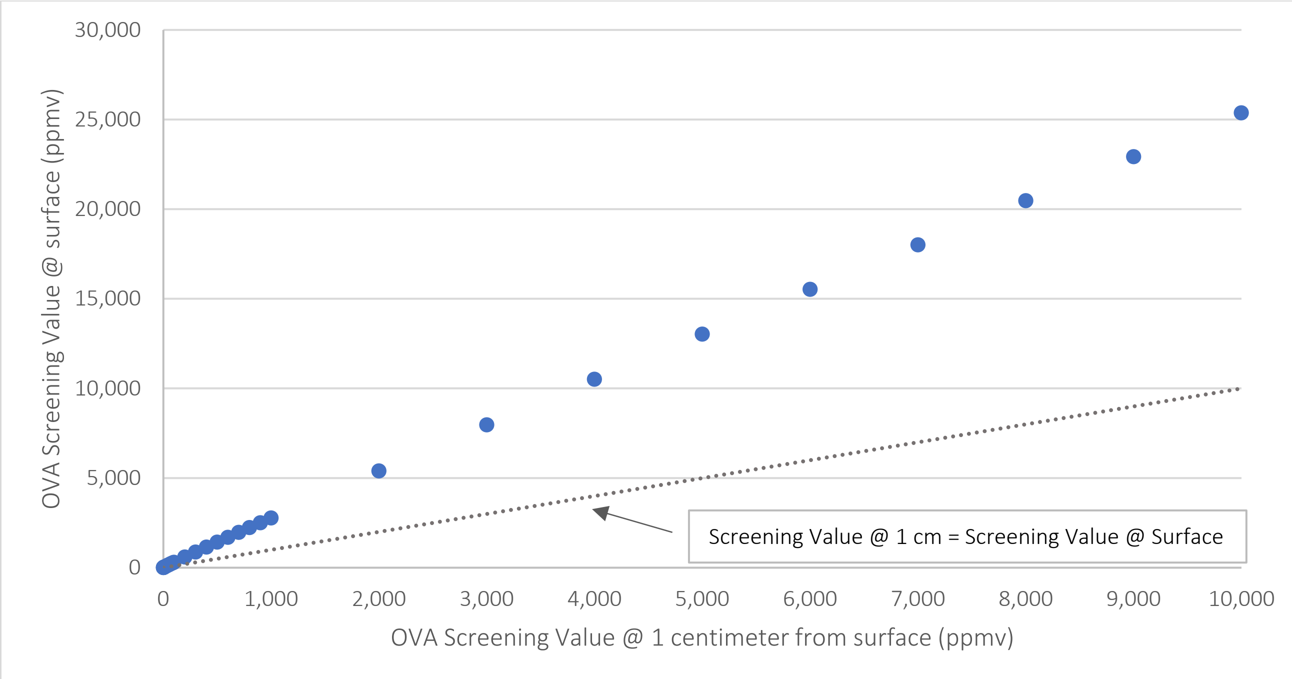

Figure I.2. OVA screening Values at 1 centimeter from surface versus at the surface

To convert screening values of different screening instruments to different screening distances, the study recommended using Equation I-1 and the correlation equations in Table I-15. Using Equation I-1 and the correlation equations for converting screening measurements between OVA and TVA FID, TVA FID screening measurements taken at 1 centimeter from the surface may be converted to TVA FID screening measurements at the surface. Plotting the results in Figure I.3 shows a significant difference between the two.

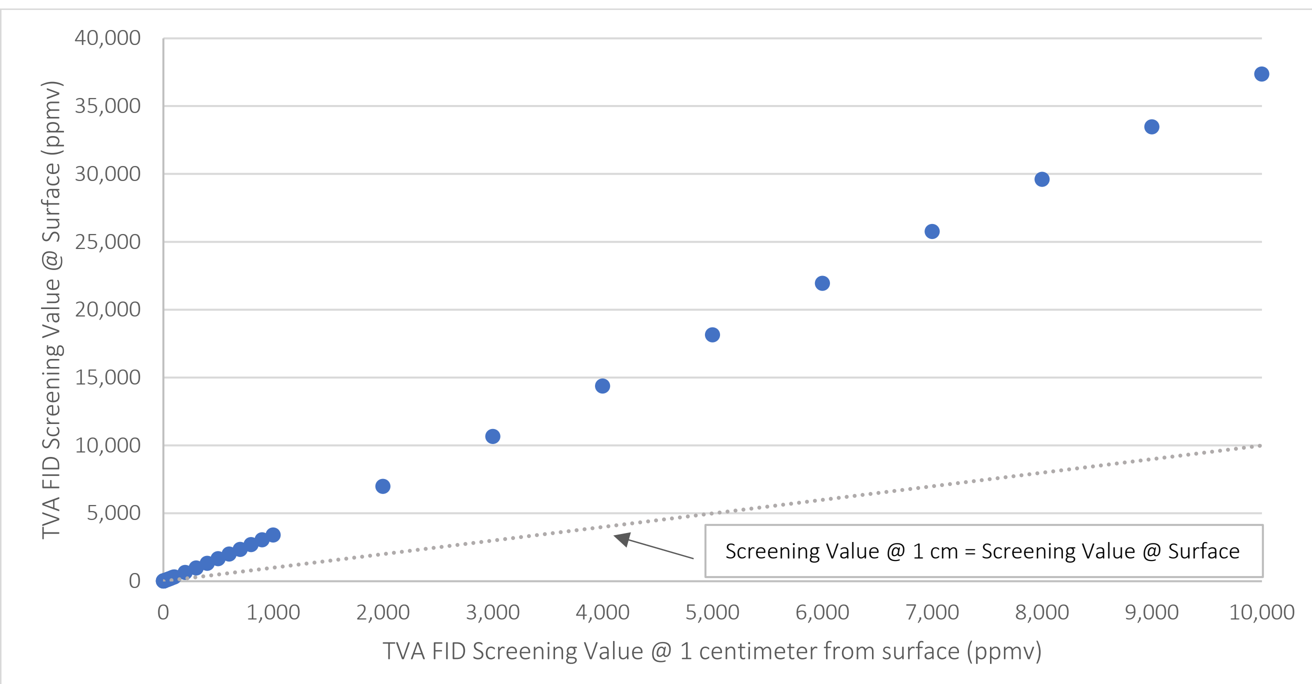

Figure I.3. TVA FID screening values at 1 centimeter from surface versus at the surface

I.iii.6. 1996 API Study

In 1996, API conducted a study to develop new average factors for equipment leaks from components in heavy liquid service. The results of the study were published in API Publication Number 337 (August 1996) *Development of Emission Factors for Leaks in Refinery Components in Heavy Liquid Service.*

The study incorporated existing screening data from four refineries in Southern California and conducted screening at two refineries in Washington State.

The screening results were combined with Method 3 correlation equations, as listed in the 1995 EPA Protocol, to derive average emission factors for components in heavy liquid service.

Two of the Southern California refineries included heavy liquid service components into their LDAR program even though screening was not required per the South Coast Air Quality Management District's (SCAQMD) Rule 1173 (Fugitive Emissions of Volatile Organic Compounds).

The other two refineries conducted heavy liquid service screening as part of a planning effort for the 1993 WSPA/API study. The following components were included in the study:

Table I-16. *API Publication 337 Study Component Counts by Refinery and Component Type*

Refinery	Component		Count	LDAR Inclusion?
CA 1	Valve		28,265	YES
	Fitting		100,482	
	Flange		23,370	
	Pump		787	
	Other		12,077	
	PRD		871	
		Total	165,852	
CA 2	Valve		5,468	YES
	Fitting		14,268	
	Flange		1,536	
	Pump		72	
	PRD		66	
		Total	21,410	
CA 3 & CA 4	Valve		10,137	Unknown
	Fitting		13,312	
	Pump		116	
	PRD		463	
		Total	24,028	
WA 1 & WA 2	Fitting		862	NO
	Flange		766	
	OEL		7	
	Other		91	
	Pump		35	
	Valve		787	
		Total	2,548	
All		Total	213,838	N/A

The California screening data was not categorized by streams. However, components at the Washington State refineries were.

Table I-17. API Publication 337 Study Component Counts by Process Stream

Refinery's Stream Description	10% Distillation Temp (Degrees Fahrenheit)		Count
300 – 499 °F, Middle Distillate, Medium			
Light Flash Distillate	340		122
Heavy/Light Gas Oil	340		112
Kerosene	349		158
Light Gas Oil	358		82
Aeronautical Turbine Fuel	360		384
Cracked Heavy Gas Oil	440		26
Cracked Hot Heavy Gas Oil	440		13
Light Catalytic Gas Oil	464		69
Circulating Reflux	470		40
Light Diesel	477		89
Cracked Very Light Gas Oil	480		28
Cracked Very Light	480		69
Heavy Gas Oil	492		163
		Sub-Total	1,355
500 – 699 °F, Middle Distillate, Heavy			
Residual # 6	500		166
Intermediate Diesel	560		52
Heavy Flash Distillate	575		230
Extra Heavy Gas Oil	590		89
Residual	615		76
Light Vacuum Gas Oil	675		146
Extra Heavy Flash Distillate			118
		Sub-Total	877
≥ 700 °F, Residual			
Atmospheric Bottoms	700		30
Heavy Vacuum Gas Oil	722		163
Heavy Vacuum Circulation Reflux	733		6
DA Oil	820		98
Asphalt	920		19
		Sub-Total	316
		Total	2,548

The study found the following equipment leak concentration rates:

Table I-18. API Publication 337 Study - Percentages of Measurements by Screening Range

	Measurements in Screening Ranges (%)					
Refinery	≤ 10	11 – 99	100 – 999	1,000 – 9,999	10,000 – 49,999	≥ 50,000
CA 1	99.88	0.03	0.06	0.01	0.01	0.00
CA 2	99.53	0.15	0.04	0.19	0.07	0.02
CA 3	99.53	0.15	0.04	0.19	0.07	0.02
CA 4	97.18	1.75	0.76	0.09	0.22	0.00
WA 1	90.30	5.06	4.22	0.42	0.42	0.06
WA 2	94.69	3.32	1.73	0.00	0.00	0.00

These rates correspond to the following approximate number of components:

Table I-19. API Publication 337 Study - Measurement Counts by Screening Range

	Measurements in Screening Ranges (ppmv)					
Refinery	≤ 10	11 – 99	100 – 999	1,000 – 9,999	10,000 – 49,999	≥ 50,000
CA 1	165,653	50	100	17	17	0
CA 2	21,310	33	9	41	15	5
CA 3	7,548	136	60	7	18	0
CA 4	13,372	2,498	280	80	23	12
WA 1	1,670	93	78	8	0	1
WA 2	662	24	12	0	0	0
Total	210,241	2,825	526	151	73	19

The study concluded the following:

- Screening values for heavy liquid service are independent of stream temperature and hydrocarbon composition (as defined by the 10% Distillation Temperature, ASTM Method D86).

- An explanation for the above conclusion was that heavier hydrocarbons, which are more viscous and less volatile at ambient temperatures, inherently circulate in higher temperature process streams.

I.iii.7. 1999 CAPCOA Guidelines

After the 1995 EPA Protocol was published, the California Air Pollution Control Officers Association (CAPCOA) identified technical concerns with the information. Starting in October 1996, CAPCOA and representatives of California air quality districts began discussions with the EPA and the petroleum industry (both WSPA and individual petroleum refineries).

In May 1997, CAPCOA produced an analysis ("Review of the 1995 EPA Protocol: The Correlation Equation Approach to Quantifying Fugitive Hydrocarbon Emissions at Petroleum Industry Facilities") of the document that justified necessary revisions.

Technical corrections and adjustments were made that resulted in revised correlation equations. These revised equations as well as procedures and methodologies for estimating fugitive hydrocarbon emissions from California petroleum facilities were published by CAPOCA in *California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities*, dated February 1999.

These guidelines included the average emission factors from the 1980 EPA Study for where routine component screening is not being conducted.

II. Methodology

An approach like previous studies was adopted for this study. Components were selected for inclusion into the study, screened for leaks, and a subset had mass emissions sampled. Not every component found leaking had mass emissions sampled due to both cost considerations as well as practical difficulties encountered in the field. As such, mass emissions sampling results were extrapolated to components where leaks were measured but were not sampled.

To reduce introducing a potential bias that may affect the validity of the study or study results, measures were taken for component selection, measurement, and analyses.

Quality assurance procedures and quality control checks were implemented to improve the accuracy and relevance of study data.

The following general principles were employed:

- use of established statistical methodologies,
- to the extent it was reasonable, the methodologies employed in deriving the existing average emission factors were followed,
- individual data were evaluated for quality assurances purposes,
- prior to excluding any data for failure to meet quality assurance procedures, discussed with the refinery that generated such data to ensure that quality assurance determinations were correct, and
- to the extent that assumptions were used, all such assumptions as well as all analyses performed were documented.

Preliminary activities included: data gathering, component identification, component selection, enforcement agreement (for components found leaking above a standard but would not have mass emissions sampled prior to a required repair requirement), standardized forms, personnel selection, and personnel training.

Components to be included within the study were identified by the Air District through refinery-provided process flow diagrams/drawings (PFDs), piping and instrumentation diagrams (P&IDs), survey information, and Air District-created test matrices.

i. Experimental Design of the Study

There are many factors or variables that may potentially affect equipment leak emissions. Prior to initiating this study, some of these variables were identified either from previous studies or from current efforts. Identifying and accounting for these variables was primarily to address two questions:

- How to find a “representative” sample?
- What factors may contribute significantly to emissions?

The first question is necessary for determining an “average” emission rate. The second question is necessary for answering the first question, both to account for any potential bias resulting from over or under sampling of components with emission-significant attributes and for estimating emissions from non-sampled components.

As the population of petroleum refinery components handling heavy liquid streams was estimated to be in the hundreds of thousands, conducting a census (sampling every component) of the entire population was not practicable nor feasible.

The following sections discuss what measures were taken for identifying and selecting components to include and exclude within the Study.

II.i.1. Refinery Selection

Although there are several refiners and re-refiners in the Bay Area, this study only included components at five petroleum refineries located within the Air District:

- Chevron Richmond Refinery (Richmond, California),
- Marathon Golden Eagle Refinery (formerly Tesoro Golden Eagle Refinery, Martinez, California),
- PBF Martinez Refining Company (formerly Shell Martinez Refinery, Martinez, CA),
- Phillips 66 San Francisco Refinery (Rodeo, California), and
- Valero Benicia Refinery (Benicia, California).

All five facilities are considered deep conversion petroleum refineries that have cracking, coking, and sulfur treating capabilities. At the time of the study, each petroleum refinery had a Nelson Complexity Index (a measure of refinery complexity and capabilities) of between 13.3 and 16.1 as stated by petroleum refinery corporate published information.

Each petroleum refinery had multiple, designated personnel that contributed to the Study in their areas of expertise.

After emissions sampling was completed but prior to issuance of this report, two of the five petroleum refineries were sold and acquired by different entities. The Tesoro Golden Eagle Refinery was sold to Andeavor, which was subsequently acquired by the Marathon Petroleum Corporation. The Shell Martinez Refinery was sold to PBF Energy. As corporate governance and corporate specific standards (e.g., design, equipment selection, inspection, and maintenance frequency) may influence emissions, the corporate entities that owned and operated the components under study are referenced in this report.

Therefore, for the purposes of this study, the Marathon Golden Eagle Refinery is referred to as the Tesoro Golden Eagle Refinery and the PBF Martinez Refining Company is referred to as the Shell Martinez Refinery. For ease of reference, each refinery will be referred to by its corporate name: Chevron, Phillips 66, Shell, Tesoro, and Valero.

Although each petroleum refinery is of a similar category (deep conversion), there are significant distinguishing features between them including age, operable capacity, size, and configuration.

Table II-1. Distinguishing Features of Petroleum Refineries Included in the Study

Refinery	Started	Size (acres)	Operable Capacity [1] (barrels/day)
Chevron	1902	2,900	245,271
Phillips 66	1896	1,110	120,200
Shell	1915	860	156,400
Tesoro	1913	2,200	166,000
Valero	1968	800	145,000

Note:
1. Operable capacity at time of emissions sampling as listed in the U.S. Energy Information Administration – Refinery Capacity Report June 21, 2017.

Each corporate entity has its own corporate standards for equipment design, selection, installation, inspection, and maintenance frequency, as well as varying criteria for when a component should be replaced. The components studied varied in age and type and therefore, may represent different company standards depending upon when the component was installed and the owner at the time. The following table lists the ownership history of the five petroleum refineries included in the Study.

Table II-2. Ownership History of Petroleum Refineries Included in the Study

Refinery [1]	Started	Ownership [2]	Ownership Years [2]
Chevron	1902	Pacific Coast Oil	1902 - 1906
		Standard Oil Company	1906 - 1926
		Standard Oil Company of California (SoCal)	1926 – 1977
		Chevron USA Inc.	1977 – 2001
		ChevronTexaco Corporation	2001 – 2005
		Chevron Corporation	2005 - Present
Phillips 66	1896	Union Oil Company of California	1955 - 1983
		Unocal	1983 – 1997
		Tosco Corporation	1997 – 2001
		Phillips	2001 – 2002
		ConocoPhillips	2002 – 2012
		Phillips 66	2012 - Present
Shell	1915	Shell Company of California	1915 – 1939
		Shell Oil Company, Incorporated	1939 – 1949
		Shell Oil Company	1949 – 1998
		Equilon Enterprises (joint venture of Shell Oil Company & Texaco, Incorporated)	1998 - 2002
		Shell Oil Company	2002 – 2020
		PBF Energy	2020 - Present
Tesoro	1913	Associated Oil Company	1913 – 1937
		Tidewater Associated Oil Company	1937 - 1966
		Phillips Petroleum	1966 – 1976
		Tosco Corporation	1976 – 2000
		Ultramar Diamond Shamrock	2000 – 2002

Refinery [1]	Started	Ownership [2]	Ownership Years [2]
		Valero Refining Company	2002
		Tesoro	2002 - 2013
		Tesoro Refining & Marketing	2013 -- 2017
		Andeavor	2017 – 2018
		Marathon	2018 - Present
Valero	1968	Exxon Company USA	1968 – 200
		Valero Refining Company	2000 - Present

Notes:

1. Denotes ownership during time of the Study.

II.i.2. Process Unit Selection

Each petroleum refinery is comprised of a dozen or more different functional areas, process areas or process units. Raw, intermediate, and finished materials are received and shipped via either pipeline, marine vessel, rail car, or trucks and stored within aboveground storge tanks located in “tank farms”, areas that include dozens of storage tanks interconnected with piping.

Process units may be generically categorized by process type and function:

- Separation
- Conversion
- Treatment
- Blending
- Support
- Storage

For pragmatic reasons, only two process units per refinery were initially targeted to be included within the study. However, although two process units per refinery were initially selected, additional process units were included to meet a target number of study components.

The following process units were included in the study:

- Crude Unit (Atmospheric and Vacuum Distillation)
- Catalytic Cracking
- Hydrocracking
- Hydrogen Production
- Delayed Coking
- Alkylation
- Fuel Gas/Light Ends Processing
- Hydrotreating,
- any other unit and/or refinery area group identified as containing heavy liquid service components.

Process units were identified and categorized according to:

- function,
- age,
- capacity,
- turnaround history,
- modification history,
- number of components
- process streams,
- operating temperature and operating pressure, and
- initial boiling points of process streams.

Process flow diagrams (PFDs) provided by the petroleum refineries were used to identify potential process units to be screened. Piping and Instrumentation Diagrams (P&IDs) provided by the petroleum refineries were used to identify potential process lines within selected process units to be screened.

II.i.3. Component Types

There are several kinds of components that handle or may handle materials classified as heavy liquid service. This study principally investigated emissions from four general classifications or types of components:

- pump seals,
- valves,
- connectors, and
- pressure relief devices that relieve to atmosphere.

Each component type has different points and mechanisms for how and where equipment leaks may occur. Leaks typically occur at gaps between mating surfaces of two or more pieces of equipment. A variety of techniques are used to mitigate potential leaks including the use of gasket materials, barrier fluids, and lubricating oils.

Some component types by their design and operation have dynamic parts such as rotating shafts, rotating or oscillating valve stems, or lift plates that are intended to move depending on the operation.

Connectors

Connector is a generic term used to describe a flanged, screwed, or other joined fitting used to connect any piping or equipment and includes sub-components of larger equipment.

Some of the various types of connectors include flanges, unions, threaded piping, compression tubing fittings, sight glasses, plugs, manways, hatches, and pressure gauges.

There are dozens of connector sub-types, but the most frequent encountered is a flange located at the end of a pipe and connected to a flange on a separate piece of pipe by bolts. A gasket is employed to prevent gaps.

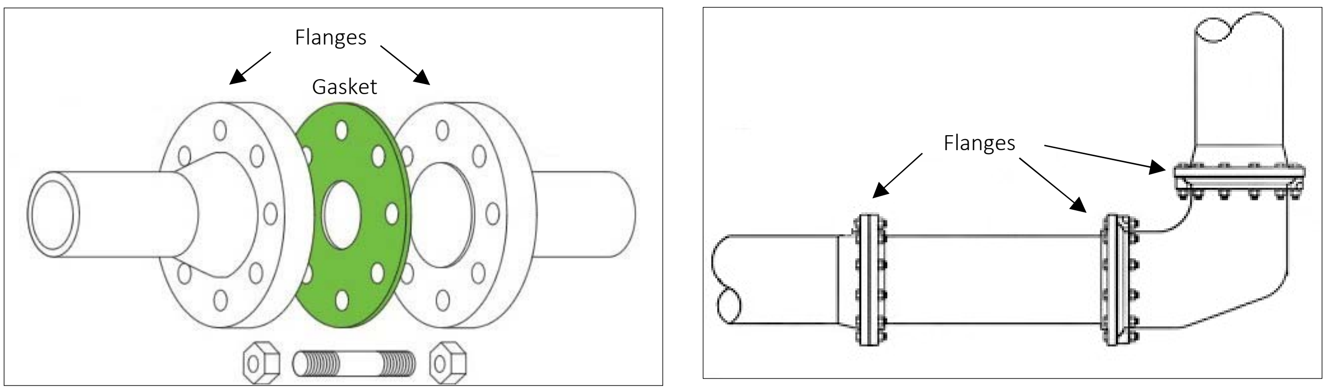

Figure II.1. *Examples of flanges*

Pump Seals

A pump is a mechanical device that moves fluids via a mechanical action where there is typically one inlet (suction) and one outlet (discharge).

Although there are dozens of different types of pumps, pumps may be broadly categorized as either dynamic or positive displacement type.

Dynamic pumps use kinetic energy to move fluids by use of an impeller (centrifugal pumps) or other mechanism (Venturi effect, cantilever, electromagnetism, etc.).

Positive displacement pumps trap and force a fixed amount of fluid to a discharge outlet via a reciprocating (piston, plunger, diaphragm, etc.), rotary (gear, lobe, screw, vane, etc.), or linear (rope, chain) mechanism.

Pumps that have a reciprocating or rotating shaft typically prevent fluid from escaping around the shaft through use of a seal (single, double, or other) where the seal could be packing, mechanical, or a barrier fluid (inert gas, hot oil, etc.).

Because of the oscillating motion (either reciprocating or rotary), escaping fluids from these pump shaft seals are expected to be the primary leak mechanism and emission source of equipment leaks from pumps. The other expected source of equipment leaks from pumps are from the pump housing and pump casing where different parts joined together using bolts. However, as these parts are static and appear like other connectors, the pump housing and pump casing are considered connectors for the purposes of the Study.

Valves

A valve controls the movement of a fluid by allowing or physically obstructing a passageway.

The primary purposes of different valves are:

- Stop (Isolation) – stop or isolate the flow of fluid to a downstream location or system,
- Regulating – control the pressure of fluid (liquid or gas) to a desired pressure, and
- Back Flow Prevention – prevent fluids from flowing in a reverse direction.

Each valve comprises multiple parts including the valve body, bonnet and bonnet flange, internal elements, actuator, valve stem, and packing material.

There are dozens of different valve subtypes although gate valves (see Figure II.2 for an example) are the most prevalent.

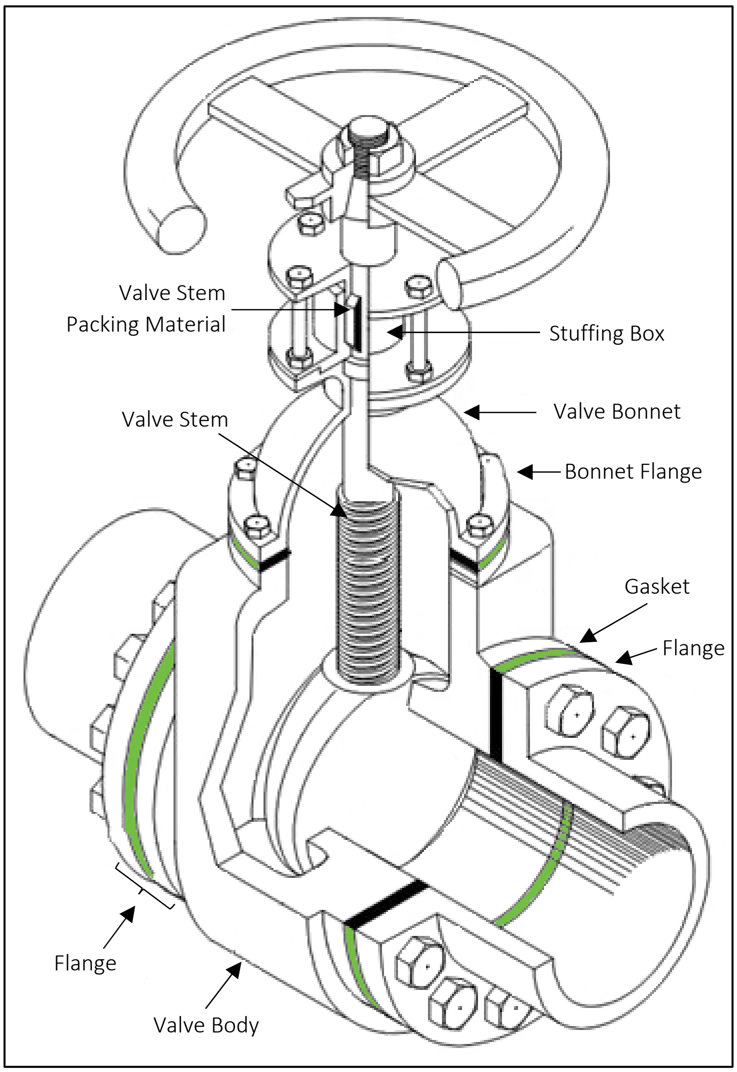

Figure II.2. Diagram of a gate valve

For regulatory compliance with Regulation 8, Rule 18, the Air District considers only the valve stem as a valve while the valve bonnet is considered a connector. This delineation was made to account for the difference in expected leak probability between a dynamic part (valve stem) and static part (valve bonnet).

Since it is difficult to isolate a valve stem from the valve bonnet for mass emissions sampling, for the purposes of the Study, both the valve bonnet and valve stem are considered a valve. However, if a valve stem were not captured in a mass emissions sample and only the valve bonnet, that sample would be considered a connector.

Pressure Relief Devices

A pressure relief device is a specialized type of device designed to protect piping and equipment from being subjected to pressures that exceed safety or design levels. When this occurs, pressure is relieved by activation of a mechanism and pressurized fluids (gas, steam, liquids, or vapors) are rerouted either to atmosphere or to separate equipment or systems (e.g., flare header).

The main types of pressure relief devices are either reclosing or non-reclosing type.

Non-reclosing-type pressure relief devices are designed to remain open once activated and include rupture disks and device pins. These devices do not have openings to the atmosphere and leaks may occur at the joint fittings, classified as connectors.

Reclosing-type pressure relief devices are designed to close after operation and include pressure safety valves and pressure relief valves and depending on the type may or may not have an opening to atmosphere. For purposes of the Study, only pressure relief valves that have an opening to the atmosphere are categorized as a pressure relief valve. A pressure relief valve that does not have an opening to the atmosphere is treated as one or more connectors because of the location (at the joint fittings rather than an opening to the atmosphere) of where equipment leaks may occur.

Pressure safety valves are designed to quickly release fluids when pressure exceeds a safety level and are opened completely once triggered.

II.i.4. Component Selection for Screening

II.i.4.1. Screening Sample Size

Previous studies have shown that equipment leaks are not normally distributed, that most equipment leaks have negligible to minor emissions while most equipment leak emissions are driven by a small minority of equipment leaks. If too small a sample size was chosen, there would be a greater probability that the study did not include a representative sample (either a large leaker was omitted, or an included large leaker would have a non-representative impact).

An appropriate sample size depended on numerous factors including a desired confidence interval, assumed leak distribution, and population size.

To determine a required sample size, the following equation, as listed in Appendix E of EPA's 1995 Protocol, was used:

$$n \geq N \, x \, [1-(1-p)^{1/D}] \qquad \text{[II-1]}$$

where:

N = total number of components in the population

D = (fraction of leaking components) x N; and

p = confidence interval (≥ 0.95)

Per EPA, the basis for selecting the sample population to be screened is the probability that at least one "leaking" component will be in the screened population. The "leaker" is used as a representation of the complete distribution of screening values for the entire class of sources.

Component Population

The population of heavy liquid service components at the five petroleum refineries included within the Study is not known. The population of such components at one petroleum refinery is known as they conducted a component inventory, identified and marked such components with physical tags, and included them within an LDAR database. However, the population of heavy liquid components at the four other petroleum refineries is not known.

The U.S. EPA published [1]a median component counts by service for process units at small and large refineries (a crude oil distillation capacity of greater than 50,000 barrels per day).

However, a review of the gas and light liquid inventories (based on actual counts) of each studied petroleum refinery indicated that the listed component counts were significantly lower than what was found through an inventory. To address this, the Air District assumed that the ratios of gas and light liquid service components to heavy liquid service components would be like the information shown in EPA's table and derived heavy liquid service component count multipliers for each listed process unit based on the number of gas and light liquid

---

[1] Table 6-9 (Median Component Counts For Process Units from Large Refineries), *Locating and Estimating Air Emissions from Sources of Benzene* (U.S. EPA, 1998).

service components in each respective process unit. These multipliers were then used with the actual gas and light liquid component counts at each petroleum refinery to estimate the number of components in heavy liquid service. However, this method only works for process units identified in the EPA table as well as those process units that have gas and light liquid service components.

The total estimated population by component type is shown below.

Table II-3. Estimated Population of Components in Heavy Liquid Service by Component Type

Component Type	Estimated Population (Start of Study)	Estimated Population (End of Study)
Valves	78,163	52,595
Pumps	2,932	1,075
Connectors	287,700	184,359
PRVs	249	594
Total	**369,044**	**238,623**

Fraction Leaking

From previous studies, emissions from components with large leaks (leaks with concentrations greater than 10,000 ppmv) dwarf those from components that leak at the leak standard.

Because the distribution of leaks is unknown, the true leak rate of individual components with large leaks (leaks with concentrations greater than 10,000 ppmv) is unknown.

If it is assumed that only one component per component type in the entire population (at all five refineries) is a large leaker, the required sample sizes per component type would be prohibitively large for valves and connectors, though not for pumps and PRVs (see Table II-4).

Table II-4. Estimated Sample Size Required from Equation II-1

Component	Population	Number of "Large" Leakers	Leak Rate (%)	Calculated Sample Size [1]
Valves	78,163	1	0.001	77,639
Pumps	2,932	1	0.03	2,898
Connectors	287,700	1	0.0003	284,606
PRVs	249	1	0.4	244
Total	**369,044**			**365,387**

Note:
1. Estimated using Equation II-1, component population, leak rate, and a desired confidence interval of 0.98

The Air District identified equipment leak concentration monitoring data taken at several Washington State refineries in the API study as being the most recent data available for this class of components. Unlike the southern California refineries that were also included in the API study, the Washington refineries did not include these components as part of an LDAR program and thus represented the best information available for understanding what fraction of components may be leaking.

In the API study, a single leaking component represented between 84 percent (1995 EPA Protocol) and 95 percent (CAPCOA) of the total estimated mass emissions from all components, depending on the set of correlation equations used. This component represented 0.04 percent of all screening values.

If a similar large leaker exists at the five petroleum refineries at the same frequency, then the required sample size with a confidence interval of 0.98 per Equation II-1 was found to be 9,652 components.

From this, a sample size of 10,000 components (2,000 per petroleum refinery) was targeted for the study.

Because of the limited number of estimated components, conducting a census (sampling the entire population) of pumps and pressure relief valves was deemed feasible. The remaining samples was targeted to be split equally between connectors and valves.

Table II-5. Target Sample Size

Component	Population	Target Sample Size
Valves	78,163	3,410
Pumps	2,932	2,932
Connectors	287,700	3,409
Pressure Relief Valves	249	249
Total	369,044	10,000

The target sample size represents less than three percent of the total estimated number of components.

II.i.4.2. Identification of Components

Since all pumps and pressure relief valves at the five petroleum refineries was targeted to be included within the Study, no method for selecting them for inclusion in the study was needed apart from identifying them using PFDs and P&IDs.

However, as the targeted number of valves and connectors represented approximately four percent and one percent of the total estimated number of valves and connectors, respectively; a method for identifying and selecting them was developed with the intention of including a diversity of components such that an emissions impactful feature was not likely to be omitted while also not resulting in a biased sample.

To minimize potentially introducing bias from selecting components in the field based on observation, components were selected for inclusion through reviews of PFDs and P&IDs at Air District offices. However, as individual valves and connectors are not shown on either PFDs or P&IDs, process lines were selected, and components located on a selected process line were included within the Study.

Because the number of components on such process lines was unknown and process lines were selected without knowledge of field conditions (e.g., selected process may be inaccessible), multiple process lines were selected and ranked in order of inclusion.

Process lines were identified and ranked according to the following variables that were identified prior to starting the Study:

- Process unit
- Function
- Operating pressure
- Operating temperature
- Component size
- Cyclic vibration
- Cyclic heating
- Process stream ASTM D86 10% temperature and/or initial boiling point
- Geographic location

Each of these variables was hypothesized as potentially correlated to emissions.

Process Unit

The 1980 EPA Study found emissions (both leak frequency and leak magnitude) to vary widely with process unit type. Therefore, process units were selected to ensure a diversity of process unit types.

Function / Component Sub-Type

Although identified as possibly correlated to emissions, the sub-types of components (e.g., gate valve, globe valve) was not readily discernible on petroleum refinery submitted P&IDs and was not used for selecting components. However, component sub-type was recorded in field sheets.

Operating Pressure and Operating Temperature

As found through physical chemistry, pressure and temperature directly impact the phase (liquid, vapor, etc.) and volume of a given material. The phase and volume of material being emitted in an equipment leak were expected to affect measured emissions.

Component Size

Component size (determined by component diameter) may have a dual effect on equipment leaks. As component size would be correlated to the size of the mating surfaces of equipment where leaks may occur, mating surface size may relate to the probability of a leak occurring. Component size may also correlate with the physical size of an equipment leak, which may impact the magnitude of leaked emissions.

Neither individual components nor their sizes were identified on P&IDs, so process piping diameter was used as a surrogate for selecting components.

Cyclic Vibration

Some components were recognized as undergoing cyclic vibration as part of normal operation. Components located on or near pumps would experience cyclic vibration whenever a pump would turn on or off. Components located on a coke drum in a delayed coking unit would experience cyclic vibration when coke cutting would cycle between coke drums or when coke would drop out of a coke drum.

With cyclic vibration, oscillating components may loosen causing gaps where equipment leaks may occur.

Components likely to experience cyclic vibration were identified as those located near or on pump stands as well as those near reactor vessels.

Cyclic Heating

Some process units (crude unit, delayed coking unit, fluidized catalytic cracking unit, etc.) require heat to drive the process and components handling such process streams can undergo cyclic heating.

Thermal expansion and contraction of component mating surfaces can cause such surfaces to move closer together or further apart potentially causing gaps where equipment leaks may occur.

In addition to temperature, the type of material a component or gasket material was comprised is critical to the degree of thermal expansion and contraction a particular component or gasket material may undergo. However, obtaining information regarding the materials of each component was deemed not feasible nor even practical if such information could be obtained. However, if cyclic heating were found to be statistically significant, a smaller study focused only on material type on emissions may be warranted.

Components likely to experience cyclic heating were identified using knowledge of the process (e.g., delayed coking cycles) as well as significant differences between process stream temperatures at intersections in process lines.

Process Stream ASTM D86 10% temperature and/or Initial Boiling Point

ASTM D86 is a standard test method used in the petroleum industry for the distillation of petroleum products at atmospheric pressure. Petroleum materials are heated and the temperatures at which certain amounts of material are vaporized (initial boiling point, 10 percent, 20 percent, etc.). Distillation temperature is one of the criteria used to classify petroleum materials and is a measure of volatility. Materials with lower distillation temperatures at atmospheric temperatures are more volatile.

Neither the ASTM D86 10% temperature nor the initial boiling point of materials handled by components was known at the time components were selected. Rather, stream material type (diesel, kerosene, jet fuel, gas oil, etc.) was known and used as a surrogate for ASTM D86 10% temperature / initial boiling point.

Geographic Location

Components may be located at ground level, on a platform, in a pipe rack, on the side of a vessel, or located over 100 feet above ground level on top of a reactor. In addition to having an LDAR program where components in gas and light liquid service are routinely monitored for leaks, each of the five petroleum refineries conduct daily audio / visual / olfactory (AVO) inspections of equipment where large leaks may be identified through hearing, sight, or smell. However, such inspections are typically down at the ground level near rotating equipment (pumps) or at key platforms. Therefore, it was theorized that a leak at a component in heavy liquid service would be more likely to be identified through AVO techniques if the component were located at ground level, near gas or light liquid components monitored by LDAR, or on a platform where operational indicators are checked.

Parameters

Obtaining a statistically significant sample population for all combinations of leak correlating parameters would have required a prohibitively large number of samples. A factorial experimental design procedure was contemplated to be used for selecting components. However, such a design required additional knowledge on the process lines and components that could only be obtained within the field. Such advanced work created logistical and practical difficulties as well as may have introduced bias from field observation of components prior to selection.

A factorial design using P&IDs may have worked. However, each process unit may have over 50 P&IDs. As each petroleum refinery has several dozen process units with heavy liquid streams, the petroleum refineries were hesitant to produce hundreds of P&IDs. Rather than label thousands of process lines and enter half a dozen to a dozen parameters for each process line into a spreadsheet for selection within a factorial design, the possible ranges of each variable were identified, and each variable was divided into levels. Process lines that met these different levels were selected for screening. A potential weakness in this selection process is that selection was not truly random. Such a process could be accomplished by numbering and categorizing each process unit within a spreadsheet program and using a randomize program selection. There were two drawbacks to this approach: 1) the length of time necessary to implement, and 2) the practical consideration of the screening teams.

The following ranges for each factor were used to select individual process lines within selected process units.

Table II-6. *Variables and Variable Ranges by Component Type*

Component	Variable	Variable Ranges (1)
Valves	Operating Pressure	-10 to 4,000 psig (or entire range)
	Operating Temperature	100 to 925 °F (or entire range)
	Function	All types (control, gate, globe, etc.)
	Size	0.5 to 36 inches (or entire range)
	Cyclic Vibration	Yes/No
	Cyclic Heating	Yes/No
	ASTM D86 10% Temp.	302 to 920 °F (or entire range)
Connectors	Pressure	-14 to 4000 psig (or entire range)
	Temperature	100 to 925°F (or entire range)
	Size	1 to 54 inches
	Function	All types
	Cyclic Vibration	Yes/No
	Cyclic Heating	Yes/No
	ASTM D86 10% Temp.	302 to 920 °F (or entire range)
All	Elevation/Location	Entire range
	Maintenance Frequency/History	Never, Semi-Frequent, Frequent

Note:
1. Variable ranges will be determined by the minimum and maximum parameter ranges that component may encounter

II.i.5. Component Selection for Mass Emissions Sampling

II.i.5.1. Mass Emissions Sampling Size

Because of cost considerations and logistics, a maximum of 20 components per refinery (100 total components) was initially selected for a mass emissions sampling size.

II.i.5.2. Identification of Components

Components with screening values of 2.5 ppmv or more above background were candidates for mass emissions monitoring.

The petroleum refineries, via a third-party contractor (Tricord Consulting), was responsible for mass emissions sampling components with screening values of 10 ppmv or more above background while the Air District would sample some leaking components (either at background concentrations or below or above 10 ppmv depending on the distribution of leaks).

If there were more than 20 components at a refinery with screening values of 10 ppmv or more above background, the components with the 20 largest screening values were selected for mass emissions sampling.

II.i.6. Modifications of the Experimental Design

During the Study, multiple changes were made to the experimental design resulting from field observations and issues arising in the field. Most of the changes were made after screening concluded at the pilot refinery.

II.i.6.1. Screening

Screening Sample Size

Conditions encountered in the field along with the initial screen procedures resulted in screening delays that significantly slowed the process.

After the pilot refinery, the target screening sample size was reduced from 2,000 components per refinery to 1,000 components. However, because previous studies had found the leak distribution to be not normally distributed, there was a concern that a reduction in sample size may not result in a representative leak distribution (e.g., if there were a larger leaker, the chance of finding it within a sample size of 1,000 components versus 2,000 components was not the same).

To address this concern, a "hypothetical" leak distribution was assumed where a minimum number of components with leaks at varying leak concentrations was assumed to exist.

If the initial screening of 1,000 components found leaks for each component type at the varying leak concentrations, screening would stop. If not, screening continued until either the leak distribution criteria were met or until 2,000 components were screened, whichever occurred first.

***Table II-7**. Assumed Leak Distribution for Purposes of Screening Sample Size*

Leak Concentration (ppmv, above background)	Assumed Minimum Number of Components (Each component type)
0 – 25	3
25 – 100	2
100 – 500	2
500 – 1,000	2
1,000 – 5,000	2

Lube Oil Components

While screening at the pilot refinery, petroleum refinery personnel were concerned that emissions from lubricating oil systems (seal oil used to lubricate pump motor bearings) would not be represented within the Study and asked field screeners to incorporate these components into their monitoring.

This was done unbeknownst to the Study lead and introduced a potentially significant bias into the Study as components were selected in the field by screening personnel based on field observations.

Once this was discovered, members of the five petroleum refineries, WSPA, and the Air District discussed the issue and agreed that the Study would only include components handling process lube oil rather than non-process lubricating oils and to remove these components from the Study.

There is currently no methodology for estimating the number of components in such lubricating systems. Therefore, emissions from these components are not included in any emissions inventory. However, the petroleum refineries were concerned that Study results may be used for such components if a methodology were developed. It was decided that emissions from these components would be studied in a separate study ("Lube Oil Study").

Steam-Quench Pumps

While screening at the pilot refinery, screening personnel encountered a type of pump that prevented screening at the required screening distance. Pumps that were designed with a steam quenching system were found to be difficult to monitor. These types of pumps used steam to remove solid particles from a pump seal as well as to prevent solidification of hydrocarbon process fluids that would cause the pump to seize. In some instances, steam from these pumps billowed at and near the seal and would condense within the screening instrument, causing it to malfunction.

Tank Farm Components

Initially, only components at process units were included within the Study. The petroleum refineries were concerned that process unit components may not be representative of the universe of components handling heavy liquid streams, in particular components that handle heavy liquid streams at atmospheric pressure and ambient temperature. The petroleum refineries requested to include components at tank farms within the Study.

Because the methodology for estimating the number of components in heavy liquid service is based on process unit type and the number of gas and light liquid service components in those process units, the number of components at tank farms has not historically been estimated nor have emissions from such components been estimated and included within the emissions inventory. Therefore, a methodology for estimating the number of heavy liquid service components in tank farms and areas other than the process units must be derived.

To accommodate this request, 200 components within the tank farms at two refineries (100 components per refinery) were targeted for screening.

II.i.6.2. Mass Emissions Sampling

Sample Size

After the pilot refinery, the maximum mass emissions sample size was increased from 20 components per refinery to 30 components per refinery. The additional 10 components were to allow for sampling of tank farm components, components with low concentration leaks, as well as stratified sampling (see *Sample Selection*).

Sample Selection

After the pilot refinery, the criteria for selecting components for mass emissions sampling was revised from the top 20 components by leak concentration to a stratified sampling where components were targeted for sampling by leak concentration range. A minimum number of components within set concentration ranges was targeted.

Table II-8. Target Number of Samples

Leak Concentration (ppmv, above background)	Minimum Number of Components to Sample			
	Valves	Connectors	Pumps	Pressure Relief Valves
0 – 25	3	3	3	3
25 – 100	2	2	2	2
100 – 500	2	2	2	2
500 – 1,000	2	2	2	2
1,000 – 5,000	2	2	2	2
5,000 – 10,000	All*	All*	All*	All*
> 10,000	All*	All*	All*	All*

Notes:
*All components within these ranges were prioritized for mass emissions sampling.

If there were not enough components found leaking with leaks in a targeted concentration range, the allotted samples for that range were distributed to one or more other ranges. This was done accounting for screening results across the petroleum refineries. For example, if one petroleum refinery did not have any components leaking in a target range but another had twice the targeted number, that refinery may have twice the number of samples taken within that range.

If there were more components in each concentration range than the target number listed in the table above, then whenever possible, components were selected to prevent over representation of any given stream (diesel, kerosene, gas oil, etc.).

For example, if there were 12 valves (four in gas oil, four in diesel, and four in kerosene service) with leaks in the 25 to 100 ppm range, then one component in each stream was selected to be sampled.

However, it was not possible to select components in different streams (due to the process unit selected). In these cases, components to be sampled were selected based on what was already sampled in a leak concentration range at a previous refinery.

Components to be sampled were categorized by concentration range, component type, stream service, and any pertinent information (operating temperature / pressure, component sub-type, etc.) and then randomly selected using a computer algorithm (Microsoft Excel’s “RANDBETWEEN” function).

If a leaking component was identified through field observation, this component was a candidate for mass emissions sampling for the purposes of developing relationships between leak concentration and mass emissions.

ii. Sampling Methodology

As 10,000 components were targeted to be screened for equipment leaks while only a fraction (less than 200 components) was targeted to have mass emissions sampled, it was necessary to derive a method for estimating emissions from non-sampled components.

As leaks from less than 200 components in the study had mass emissions measured, mass emissions from most Study components had to be estimated from data collected during the field screening. Most of the field screening data that was collected included external temperatures of the components, component type, component size, process unit, component elevation in addition to leak concentration measurements.

II.ii.1. Screening Procedure

Air District field personnel (Air Quality Inspectors) monitored ("screened") components on selected process lines for equipment leaks using a flame ionization detector (FID) following the procedures outlined in U.S. EPA Method 21 (a copy has been included in Appendix A) as listed in 40 Code of Federal Regulations Part 60 Appendix A-7 with exceptions listed in this section.

The specific manufacturer and model FID instrument used was the Thermo Fisher Scientific TVA 2020 Toxic Vapor Analyzer.

Personnel were instructed to screen components at the interface whenever possible but not more than one centimeter from the interface.

As connectors typically outnumber valves between three to one and four to one, screening personnel were advised to screen every third connector encountered in a selected process line.

Screening personnel were instructed to use the following monitoring technique:

- Place the instrument probe at the surface of the component interface where leakage would occur,
- Move the probe along the interface periphery at a 90-degree angle to the interface while observing the instrument reading,
- Identify the location of maximum leakage by moving the probe around the entire interface, and
- Keep the probe at the location of maximum reading for at least three times the response time of the instrument.

Screening personnel were advised that monitoring should not be conducted faster than four seconds per component circumferential inch monitored. However, this maximum speed was originally developed for monitoring components in gas and light liquid service.

Prior to initiating screening at the pilot refinery, Air District personnel conducted several trial runs at a petroleum re-refiner to understand any potential differences that may exist between screening components handling gas and light liquid streams and those handling heavy liquid streams. In addition, one of the petroleum refineries provided samples of heavy liquid material (gas oil, etc.) where this material was heated over a Bunsen burner to varying temperatures and produced vapors were measured with an FID to understand the instrument response to such materials. Both the field experience at the re-refiner as well as observations from the heated material indicated that the instrument measurement readings increased more slowly and decayed more slowly once the probe was removed from the emissions source than when monitoring gas or light liquid materials. From this experience, screening personnel were informed that monitoring pace may be dictated by the specific streams being monitored and their operating conditions.

Standardized field sheets were utilized to capture the following information:

- Refinery
- Screening personnel name
- Date
- Windspeed / Direction
- Monitoring instrument serial number
- Entry ID
- Process Unit / Area
- Sub-Area
- Component Type
- Component Sub-Type
- Component Size (inches)
- Stream Service
- Vibration Amount (None, Low, High)
- Cyclic Vibration (Yes / No)
- Elevation
  (Ground, Platform, Top of Vessel / Column, Other)
- Operating Temperature (degrees Fahrenheit)
- Operating Pressure
  (pounds per square inch gauge)
- Screening Time
- Background Screening Measurement (ppmv)
- Component Screening
- Maximum Measurement (ppmv)
- Comments

Either a standard 6-inch ruler, 12-inch ruler, or a measuring tape were used to estimate the diameter of the process line for a connector, diameter of a valve body, or rotating shaft for a pump seal. Because of the elevated temperatures of the components, only a sight estimate was made.

In most cases, stream service was identified either by markings on the selected process line or a nearby process line that was connected to the selected process line. In some cases, a process unit operator or supervisor provided this information.

Operating temperature was difficult to ascertain without going into a process unit control room. Therefore, the external temperature of a component's part closest to the process stream was chosen as a surrogate. A portable infrared, non-contact thermometer was used to determine the external component temperature at the point closest to the process fluid. For example, for a flange, the temperature at the innermost point of the flange was targeted as it would be nearest the temperature of the process fluid (see Figure II.3). For a valve, the external temperature of the valve body was measured.

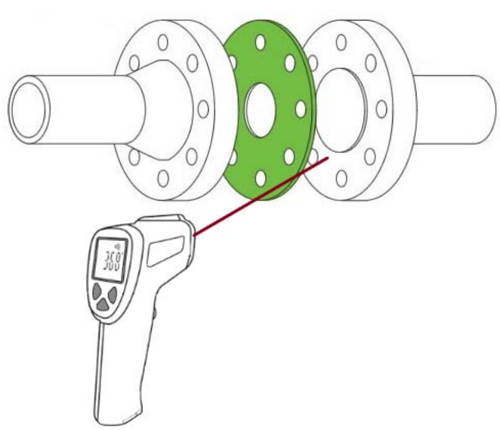

Figure II.3. Infrared temperature measurement of inner part of flange

For leaks above an applicable leak standard (100 ppmv for valves and connectors, 500 ppmv for pumps and pressure relief valves), petroleum refinery personnel verified the leak measurement using a separate FID instrument.

Each monitored component found leaking (greater than 2.5 ppmv above background) was digitally photographed for use in future locating the component (if selected for mass emissions sampling) as well as to document the state of the component at the time of component screening. A standard twelve-inch ruler was placed in the picture frame as a reference for scale. Each picture included a marker (dry-erase board) listing the component test number and maximum leak measurement value as well as a marked location of the maximum leak. A physical tag was also affixed to the component that included the component test number, date, time, and maximum screening value.

II.ii.2. Mass Emissions Sampling

Sampling for purposes of measuring mass emissions of selected components was done by enclosing ("bagging") components with Mylar® or aluminum sheets and capturing emissions in sampling media in accordance with U.S. EPA "Mass Emissions Sampling", Chapter 4.0 of the 1995 EPA "Protocol for Equipment Leak Emission Estimates". Specifically, the "vacuum method" identified in Section 4.2.1 of that chapter – with additional modifications / clarifications identified below to address components in heavy liquid service – was used. There were also further modifications made after testing at the pilot refinery was completed and the results analyzed.

Prior to mass emissions sampling, both the background (as defined in U.S. EPA Method 21) and the selected component were screened using an FID, and the maximum screening value was recorded.

If the leak concentration of the selected component was no longer within the target concentration range, another component with a screening value within the target concentration range was selected, as much as practical.

Samples were collected using sorbent tubes to capture heavier organic compounds expected to be present.

Each sorbent tube consists of multiple parts (Figure II.4) that include a primary sorbent layer (the front half), a backup sorbent layer (back half) in case of sample breakthrough, separators (wool, foam, or other material) for uniform pressure drop, and two sealing end caps that prevent sample contamination. The dimensions of the tube and the type of sorbent material vary based upon the specific model tube.

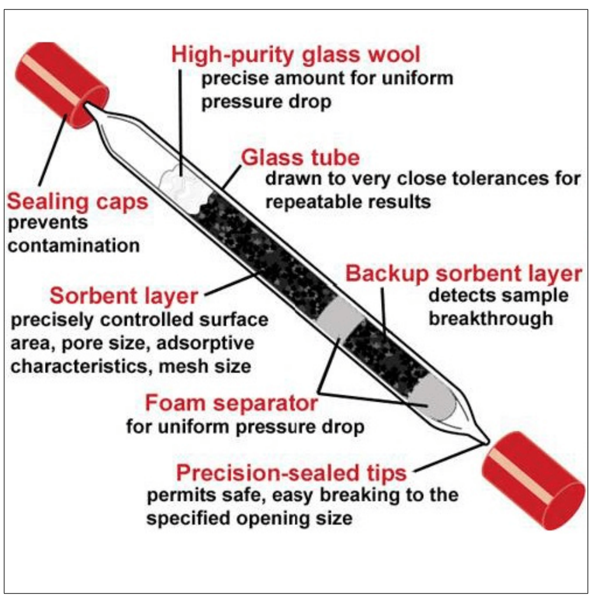

Figure II.4. Sorbent Tube Parts
(Source: SKC website: https://www.skcltd.com/products2/sorbent-tubes/charcoal-sorbent-tubes.html)

Samples were pulled through two coconut charcoal tubes in series at a sampling flowrate of approximately 1 liter per minute. Under certain conditions, a XAD-2 tube was placed in line before one to two charcoal tubes. If a XAD-2 tube was used, the sampling flowrate was reduced to 0.75 liters per minute. The third-party's sampling flowrate for sampling trains with XAD-2 tubes was limited to 0.3 liters per minute due to equipment issues. Primary and replicate samples were taken simultaneously.

The specific sorbent tubes used were the XAD-2 resin tubes (SKC catalogue number 226-30-06) and coconut charcoal tubes (SKC catalogue number 226-16).

The specific XAD-2 tube selected was 8 mm in outer diameter and 110 mm in length and had 400 mg of resin sorbent in the primary sorbent layer (front half), 200 mg of sorbent in the backup sorbent layer (back half), and glass wool separators for uniform pressure drop.

The coconut charcoal tubes were 10 mm in outer diameter and 110 mm in length with 800 mg of sorbent material in the primary sorbent layer (front half) and 200 mg of sorbent in the back half and used glass wool before the front half and foam in between layers and after the back half for uniform pressure drop.

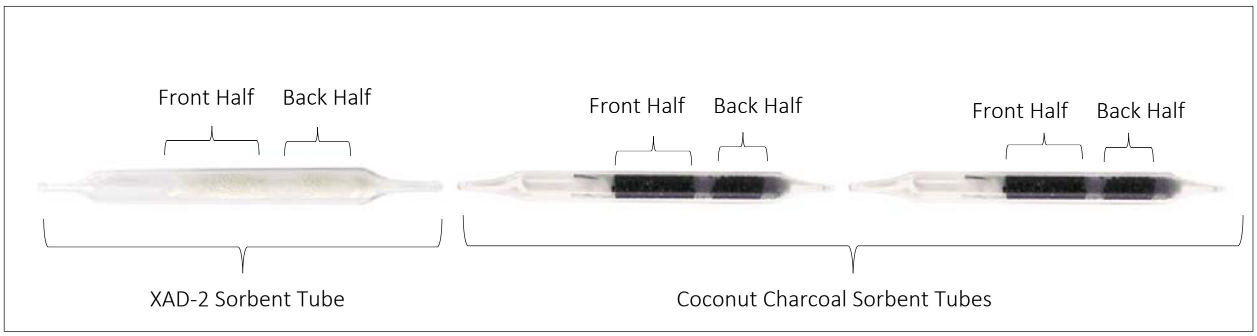

Figure II.5. *Sorbent Tubes in Series*

A total sample volume of approximately 12 liters was targeted, although some exceptions may have been made depending upon measurements taken from a continuous handheld analyzer.

For some components selected by the Air District, summa cannisters were taken for purposes of evaluating the extent to which lighter organic compounds (C_1 to C_4) and toxic organic compounds were present.

Each mass emissions sample included a sample train with sorbent tubes in line with small pumps as well as a larger pump to pull excess sample and ensure there was a vacuum in the bag around the component.

The sampling train was checked for leaks prior to testing with an allowable tolerance of ± 5 percent.

The sampling train differed from Figure 4-1 of the 1995 U.S. EPA “Protocol for Equipment Leak Emission Estimates” because heavier hydrocarbons were being targeted. In particular, the following changes were made:

- The sampling media was moved upstream of the gas meter,
- No cold trap prior to sorbent tubes, and
- Sampling bag (and sampling pump upstream of it) were replaced by sorbent tubes (and a sampling pump downstream of it).

Additionally, the following changes were optional:

- The dry gas meter replaced by a rotary gas meter,
- Digital manometers used, and
- A pump and mass flow controller used in place of personal sampling pumps.

There were also two sampling trains rather than one, to allow for one train to be used for a spike recovery study (per Section 8.4.3 of U.S. EPA Method 18).

Per page 4-8 of the 1995 U.S EPA Protocol, for each component sampled, two samples were taken using the sampling train. Spike recovery studies were targeted to be conducted on at least 15 percent of the components. The flow rate pulled through the dry gas meter was targeted to be approximately 5 liters per minute, but the operator had the ability to adjust this to keep the bag vacuum within the target range. The component bag vacuum was targeted to be 0.001 to 0.1 inches H_2O.

When canister samples were taken, cold traps were used to avoid deposition in the canisters. Flow to the 6-liter cannisters was controlled using a 0.009-inch critical orifice.

The various sampling train configurations used are shown in Figure II.6, Figure II.7, Figure II.8, and Figure II.9

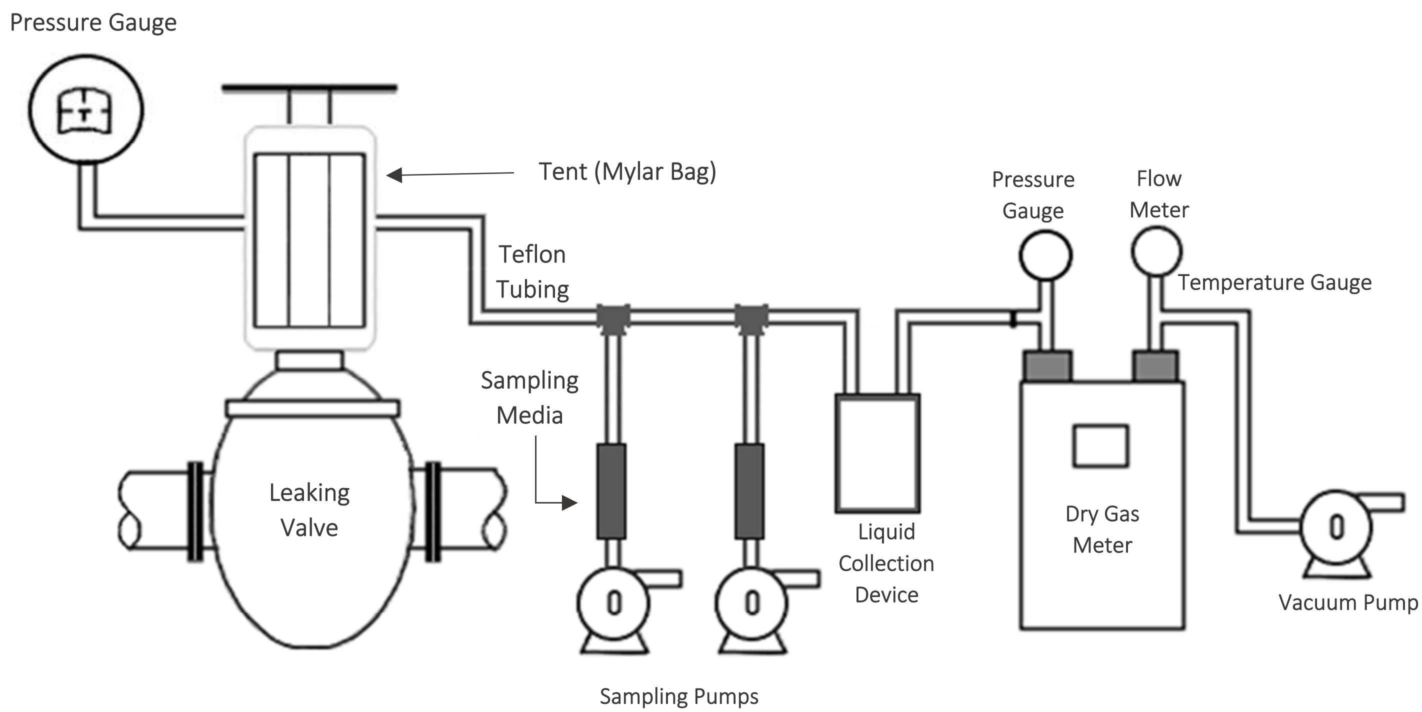

Figure II.6. Mass Emissions Sampling Train for Sorbent Tubes

II.ii.3. Modification of the Experimental Design

Screening

Field personnel were initially instructed to screen every third connector encountered on selected process lines. This instruction was to provide for an equal number of valves and connectors within a variety of process units. However, once screening began at the pilot refinery, field personnel observed that selected process lines were often insulated (heavier streams typically required higher temperatures) and connectors were not accessible.

In these instances, field personnel were instructed to estimate the number of accessible connectors and determine a monitoring frequency based on the estimated number of valves and accessible connectors. If the number of accessible connectors roughly equaled the number of valves on a selected process line, then every accessible connector was to be screened. If the number of accessible connectors was double the number of valves, then every second accessible connector would be screened.

In situations where the number of accessible connectors outnumbered the number of accessible valves by more than three to one, screening personnel decided upon a periodicity (e.g., every 10th, 25th, etc. component) and followed that periodicity. This most often occurred at the ends of air-cooled heat exchangers (fin fan coolers) where there were hundreds of connectors (threaded plugs / bolts). For air-cooled heat exchangers, screening personnel were instructed to screen every 25th connector using a zig-zag pattern (**Figure II.10**) starting at either the first top or bottom connector.

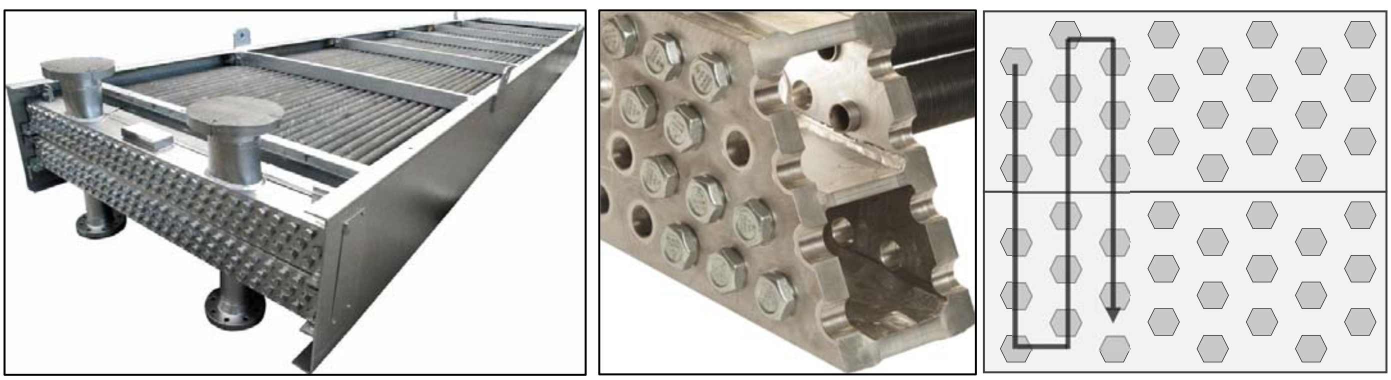

***Figure II.10**. a. Air-cooled heat exchanger, b. Close-up of threaded plugs, c. Example of screening procedure of threaded plugs*

Pulsing Leaks

While screening at the pilot refinery, multiple components were found to have pulsing leaks, where the magnitude of a screening measurement would oscillate. Potential causes of this oscillation could have been equipment vibration or operational conditions. The cause of such pulsing leaks could not be identified and was not pursued. However, as the Study protocol required recording the maximum screening measurement of each leak, care was taken to monitor the leak and identify what may be considered the maximum value. In several cases, significant time (half an hour or more) was spent on such leaks.

After the pilot refinery, specific guidance was developed for pulsing leaks. Components were screened until the screening value peaks and then for one additional minute or longer depending on the periodicity (as determined in the field) before recording the reading. Screening personnel were instructed to take consideration for pulsing leaks that increased in value (see **Figure II.11**).

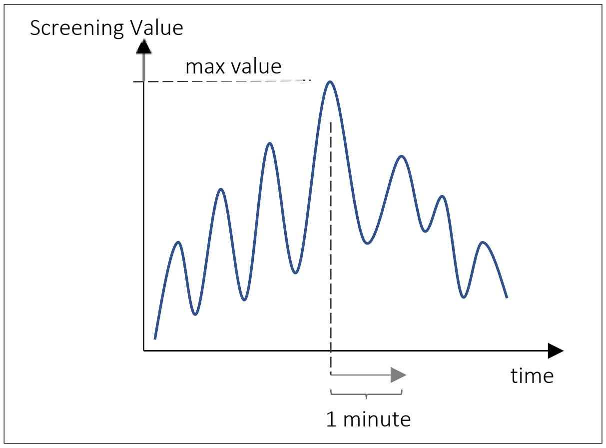

Figure II.11*. Pulsing leak*

Leak Definitions

At the pilot refinery, components with screening values of 2.5 ppmv above background were identified as "leaks" and were digitally photographed and had physical tags affixed. However, because of the volume of such components found at the pilot refinery and the amount of time this process required, only components found leaking at 25 ppmv or more above background at subsequent refineries were identified as "leaks".

Screening Personnel

In the middle of screening at the second refinery, there was a safety stand down resulting from two personal gas alarms detecting unsafe levels of carbon monoxide within a selected process unit. All screening was halted, and a review of the health and safety of the screening personnel (Air District Air Quality Inspectors) was surveyed. Several screeners told surveyors that they had been experiencing various health symptoms during screening at both the first and second refineries. Stated symptoms varied from headaches and nausea to heat exhaustion (from standing for prolonged periods near high temperature reactor vessels).

At this point, the Air District determined that it would no longer use Air District personnel to screen components and the Study could not proceed. The five petroleum refineries requested to continue the Study by using their LDAR personnel (either refinery employees or third-party contractors) who had years of experience screening gas and light liquid components and handling the hazards that are associated with such screening.

As use of different refinery personnel at each refinery for screening components could introduce an additional source of bias, third-party auditors were employed to review the screening at each petroleum refinery. One third-party auditor was a former Air District Air Quality Inspector who had retired from the Air District. However, as screening was done by petroleum refinery personnel, screening at each petroleum refinery was conducted in parallel rather than sequentially. This necessitated having multiple third-party auditors. The Air District was unable to locate an additional third-party auditor that did not have experience working for one of the five petroleum refineries. Therefore, an existing petroleum refinery LDAR third-party contractor was selected and used at the petroleum refineries for which the company had not previously been contracted.

Screening Instruments

Refinery screening personnel were instructed to ensure that screening instruments were given at least 15 minutes to warm up at the beginning of each screening day before they were calibrated.

Weather

To protect screening instruments from malfunction as well as ensure representative measurements, screening was delayed or called off when the weather forecast predicted rain.

Mass Emissions Sampling

Primary and Replicate Samples

At the pilot refinery, replicate samples were taken sequentially after primary samples. However, although the time between primary and replicate sampling was minimized as much as practical, differences between the samples could not be separated from potential operational differences nor differences in the component leak being sampled at the different times.

At the second and subsequent petroleum refineries, primary and replicate sampling were taken concurrently except when spike samples were run.

Background Samples

At the pilot refinery, a minimum of one background sample per process unit per day was taken. At subsequent refineries, one background sample was collected for every component sample.

Sampling Media and Analysis

From preliminary laboratory results of mass emissions sampling conducted at the pilot refinery, the presence of C_{25} to C_{30} hydrocarbons was not found to be moderate or significant contributors to total sample results and the use of a XAD resin tube was no longer required for every sample. Breakthrough did not appear to be an issue as well. After the pilot refinery, each sample train consisted of two series-connected charcoal tubes.

Sampling Pump Flow Rate

Because a XAD tube was no longer required after the pilot refinery, the sampling rate was increased to one liter per minute (from 0.75 liter per minute).

Condensate

Starting with Refinery B, condensate samples were collected only when liquid formed and pooled in the bottom of a sample bag. Solid matter that accumulated on the surface of the bag was not classified as “condensate”. All condensate samples were collected in VOA vials and analyzed for C_5 to C_{30} hydrocarbons.

iii. Identification of Emitted Species

Sorbent Tubes

Samples collected using sorbent tubes as well as any collected condensate were analyzed using the analytical procedures in U.S. EPA Method 18 – Measurement of Gaseous Organic Compound Emissions by Gas Chromatography (listed in 40 CFR Part 60, Appendix A). Standards and samples were analyzed following the procedures specified in Section 8.2.4 (Adsorption Tube Procedure).

For sorbent tubes, total hydrocarbon emissions for compounds with five or more carbon atoms were targeted. At a minimum, laboratory analyses were targeted to identify C_5 to C_{24} hydrocarbons. Samples were analyzed for the C_5 to C_{24} n-alkanes and others as C_X compounds. When condensate was collected or if XAD-2 tubes were used, the laboratory was instructed to target C_5 to C_{30} hydrocarbons.

Sample tubes and collocated spike samples (see Quality Assurance and Quality Control section for discussion of spike samples) were desorbed into two fractions (the front half and the back half) where each fraction was desorbed using 2.0 mL of carbon disulfide and shaken at a speed of 450 revolutions per minute for 30 minutes. Each fraction was analyzed separately, and results summed.

For spiked samples, proportional aliquots were combined from the two fractions to permit a single analysis.

Sampling media for replicates, background, and trip blank samples were desorbed whole using 4.0 mL of carbon disulfide and shaken at a speed of 450 revolutions per minute for 30 minutes.

Samples were analyzed using an Agilent Technologies Model 7890A, Gas Chromatograph "Ralph" and the Hewlett Packard Model 5890, Series II Gas Chromatograph "Teller", each was equipped with an FID.

The choice of detector was based upon the target analytes and the potential constituents within the sample being analyzed.

Carbon number retention time windows were established and all peaks within that window were quantitated using the response factor of the associated n-alkane. To capture analytes after C_{24}, the gas chromatograph was run for an additional five minutes after the C_{24} eluted and any mass associated with peaks eluting after C_{24} were quantified using the response factor of the last calibrated peak (C_{24}).

The choice of gas chromatograph column and the range and rate of oven temperature ramping was based upon the target analytes and the potential constituents within the sample being analyzed.

The choice of oven temperature ramping rate and range was determined by considering the composition, initial boiling point, operating temperature, and operating pressure of the process stream handled by the equipment being sampled.

Evacuated Canisters

Samples collected in evacuated canisters and in liquid collection devices were analyzed per:

- U.S. EPA Method 18 – Measurement of Gaseous Organic Compound Emissions by Gas Chromatography (listed in 40 CFR Part 60, Appendix A)
- U.S. EPA Method TO-14A – Determination of Volatile Organic Compounds (VOCs) In Ambient Air Using Specially Prepared Canisters with Subsequent Analysis by Gas Chromatography (from U.S. EPA *Compendium of Methods for the Determination of Toxic Organic Compounds in Ambient Air – Second Edition*, EPA/625-R-96/010b).
- U.S. EPA Method TO-15 – Determination of Volatile Organic Compounds (VOCs) In Air Collected in Specially-Prepared Canisters and Analyzed by Gas Chromatography / Mass Spectrometry (GC/MS) (from U.S. EPA *Compendium of Methods for the Determination of Toxic Organic Compounds in Ambient Air – Second Edition*, EPA/625-R-96/010b).

For evacuated canisters, C_1 to C_4 hydrocarbons and specific toxic air contaminants were targeted.

Limitations

U.S. EPA Method 18 was identified as having several limitations regarding compounds that:

- are polymeric (high molecular weight)
- can polymerize before analysis, or
- have very low vapor pressures at instrument conditions.

Laboratory Analysis

The laboratory ran into challenges when analyzing larger data sets and could no longer reliably break down C_{25}-C_{30} into separate C_n windows. As a result, the data sampled by the Air District at the pilot refinery was analyzed for C_5 to C_{30}, the data sampled by Tricord at the pilot refinery was analyzed for C_5 to C_{24}, and the data sampled at subsequent refineries was analyzed for C_5 to C_{24} with the sum of C_{25}-C_{30} reported as C_{24}.

During analysis of the pilot refinery samples, one of the goals was to determine whether there was an adequate amount of sampling media to prevent breakthrough. The front and back halves of the first charcoal tube were combined with the front half of the second charcoal tube to form the first fraction while the back half of the second charcoal tube was analyzed as the second fraction. As it was established that breakthrough was not occurring, later analysis involved analyzing the front and back half of the first charcoal tube separately and archiving the second tube. By doing so the laboratory was able to use less solvent and minimize detection limits.

Calculation of Sample Emission Rates

From laboratory analysis results, a total hydrocarbon emission rate for each sample was calculated where the total hydrocarbon emission rate was derived from emissions measured on sorbent tubes as well as from any condensate collected with a sample.

$$\text{Sample THC Emission Rate} = \sum_i \left(\text{Gas/Vapor Emission Rate}_{\ (i)} + \text{Liquid Emission Rate}_{(i)}\right) \qquad \text{[II-2]}$$

where:

Sample THC Emission Rate	= Sample total hydrocarbon emission rate, (kg/hour)
Gas/Vapor Emission Rate $_{(i)}$	= Emission rate of species (i) within sampling media (charcoal tube or XAD tube), (kg/hour), see Equation II-3
Liquid Emission Rate $_{(i)}$	= Emission rate of species (i) of any liquid collected during sampling, (kg/hour), see Equation II-9

$$\text{Gas/Vapor Emission Rate}_{\ (i)} = \text{Sample THC Emission Rate} = \left[\frac{\text{Sample Mass}_{(i)}}{\left(\frac{\text{Sample Run Time}}{60}\right)}\right] \times \left[\frac{1}{1{,}000{,}000{,}000}\right] \qquad \text{[II-3]}$$

where:

Gas/Vapor Emission Rate$_{(i)}$	= Emission rate of species (i) within sample, (kg/hour)
Sample Mass $_{(i)}$	= Mass of species (i) within sample, (μg)
Sample Run Time	= Amount of time sample run was conducted, (minutes)
60	= Conversion factor (minutes per hour)
1,000,000,000	= Conversion factor (micrograms per kilograms)

$$\text{Sample Mass}_{\ (i)} = \left[\frac{\text{Adjusted Sample Concentration}_{\ (i)}}{1000}\right] \times \text{Total Run Volume} \qquad \text{[II-4]}$$

where:

Adjusted Sample Concentration$_{(i)}$	= Sample concentration of species (i) adjusted for trip blank and background, (μg/m^3), see Equation II-5
Total Run Volume	= Total volume of gas during sample run, (L)
1000	= Conversion factor (liters per cubic meter)

Sample results of individual species were adjusted by subtracting any amount of that species found in both a background sample taken of the same process unit as the component sampled as well as for any amount found in a trip blank that accompanied the samples (component and background) from the field to the laboratory.

For any species that was not detected above the detection level within the sample, one-half of the detection limit for that species was assumed to be present in the sample. This assumption did not apply to either the background or trip blank samples as the species was not expected to be present in the ambient environment.

$$\text{Adjusted Sample Concentration}_{(i)} = [\text{Component Sample}_{(i)} - \text{Trip Blank}_{(i)}] - [\text{Background Sample}_{(i)} - \text{Trip Blank}_{(i)}] \qquad \text{[II-5]}$$

where:

Adjusted Sample Concentration$_{(i)}$	= Sample concentration of species (i) adjusted for trip blank and background
Component Sample$_{(i)}$	= Concentration of species (i) in component sample run
Trip Blank$_{(i)}$	= Concentration (μg/m^3) of species (i) in trip blank sample
Background Sample$_{(i)}$	= Concentration (μg/m^3) of species (i) in background sample

$$\text{Total Volume} = \text{Sample Volume} + \text{Dry Gas Meter Volume} \quad \text{[II-6]}$$

where:

Total Volume	= Volume of gas during sampling, (L)
Sample Volume	= Volume of gas pulled through sampling media, (L), see Equation II-7
Dry Gas Meter Volume	= Volume of gas pulled through dry gas meter during sampling, (L), see Equation II-8

$$\text{Sample Volume} = [\,\text{Volume}_{\text{Run A}} + \text{Volume}_{\text{Run B}}] \times \left[\frac{\text{Barometric Pressure} - \text{Vacuum}}{760}\right] \times \left[\frac{294.15}{\text{Sample Temperature}}\right] \quad \text{[II-7]}$$

where:

Sample Volume	= Total volume of gas during sample run, (L)
Volume $_{\text{Run A/B}}$	= Volume of gas pulled through sorbent media during each run, (L)
Barometric Pressure	= Pressure reading during sampling, (mm Hg)
Vacuum	= Dry gas meter vacuum, (mm Hg)
760	= Conversion factor for standard pressure, (mm Hg)
294.15	= Conversion factor for standard temperature, (Kelvin)
Sample Temperature	= Temperature of gas at outlet of sample pump A, (Kelvin)

$$\text{Dry Gas Meter Volume} = [\text{DGM Flow Rate}] \times \left[\frac{\text{Barometric Pressure} - \text{Vacuum}}{760}\right] \times \left[\frac{294.15}{\text{Sample Temperature}}\right] \times [\text{Sampling Time}] \quad \text{[II-8]}$$

where:

Dry Gas Meter Volume	= Volume of gas pulled through dry gas meter during sampling, (L)
DGM Flow Rate	= Dry gas meter flow rate, (liters/minute)
Barometric Pressure	= Pressure reading during sampling, (mm Hg)
Vacuum	= Dry gas meter vacuum, (mm Hg)
760	= Conversion factor for standard pressure, (mm Hg)
294.15	= Conversion factor for standard temperature, (Kelvin)
Sample Temperature	= Temperature of gas at outlet of sample pump A, (Kelvin)
Sampling Time	= Total sampling time, (minutes)

$$\text{Liquid Emission Rate}_{(\text{i})} = \left[\frac{\text{Sample Mass}_{(\text{i})}}{(\text{Sample Run End Time} - \text{Bag End Time})}\right] \times \left[\frac{60}{1{,}000{,}000{,}000}\right] \quad \text{[II-9]}$$

where:

Liquid Emission Rate $_{(i)}$	= Emission rate of species (i) of any liquid collected during sampling, (kg/hour)
Sample Mass $_{(i)}$	= Mass of species (i) within sample, (µg)
Sample Run End Time	= Time sample run was completed
Bag End Time	= Time that component enclosure was completed and reached equilibrium
60	= Conversion factor (minutes per hour)
1,000,000,000	= Conversion factor (micrograms per kilogram)

iv. Quality Assurance and Quality Control

Quality assurance (to prevent deficiencies from occurring) and quality control (to identify deficiencies once occurred) procedures were implemented prior to, during, and after the Study to improve the accuracy and precision of Study results.

Terms used in this section (and Study) include accuracy, precision, resolution, range, and error, which have the following meanings:

Accuracy – how close a measurement is to the "true" (actual value).

Precision – how close two or more measurements are to each other under the same conditions, regardless of whether those measurements are accurate or not. Precision is a measure of the spread of different readings and reflects the reproducibility of a measurement.

Resolution – the smallest discernible change in the parameter of interest that can be registered by a particular instrument.

Range – the extent over which an instrument can reliably function within the confines of its specification.

Error – the amount by which an assumed value deviates from its true value

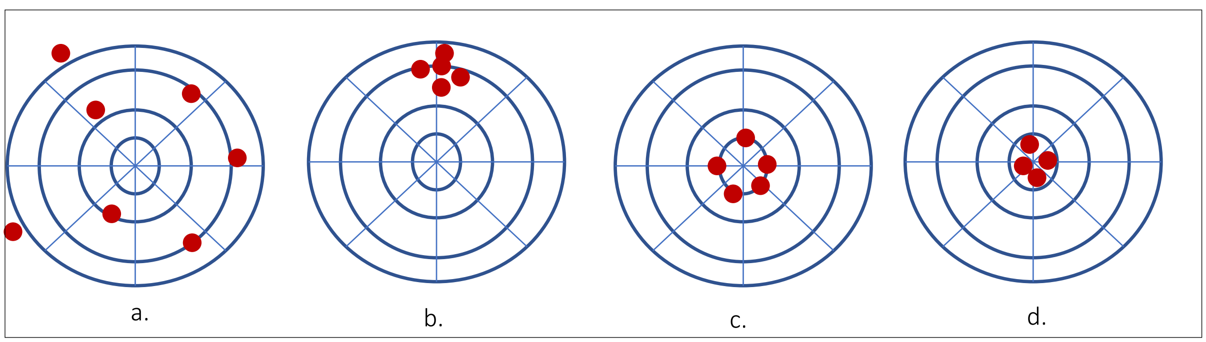

Figure II.12. Example of a. not accurate, not precise, b. not accurate, precise, c. accurate, not precise, d. accurate, precise

The specific quality assurance and quality control processes and checks varied for the different Study phases.

II.iv.1. Screening

Potential areas in component screening that may introduce errors in the Study include component selection, personnel, screening instrument, screening procedure, and information capture and recording.

Process lines were pre-selected from drawings (PFDs and P&IDs) offsite of the petroleum refineries and identified in the field with assistance from petroleum refinery process unit operators or area supervisors.

As much as practical, the same personnel were used in screening. However, as discussed above, after the pilot refinery, petroleum refinery personnel were used to screen components at their respective refineries. As such, the same personnel could not be used for all five petroleum refineries.

To address this variable, several training sessions were held for both Air District and petroleum refinery personnel to discuss and outline the established screening methodology and expected monitoring technique. A particular emphasis was placed on distinguishing the differences between LDAR monitoring gas and light liquid service components for regulatory purposes where the intention is to find and fix leaks and monitoring heavy liquid service components for the purposes of developing average emissions factors. It was explained that the instrument response time for heavy liquid service leaks would be longer than gas and light liquid leaks, so the monitoring pace was expected to be slower. In addition, unlike for regulatory compliance where it is more important to determine whether a leak is above or below a leak standard, it was important that the most accurate screening measurement be taken and that this would also be expected to result in longer monitoring times.

Instrument Specifications

Prior to initiating the Study, a survey of portable hydrocarbon equipment leak measuring devices was conducted to identify the manufacturer and model of instrument that was judged to both accurate and precise of measuring organic compound concentrations from equipment leaks. The Thermo Fisher Scientific TVA2020 Toxic Vapor Analyzer was identified as such. The Air District already had some of these instruments for auditing equipment leaks at petroleum refineries and chemical plants for regulatory compliance purposes. However, the Air District purchased additional instruments for the Study. In addition, most of the petroleum refineries were already using this model instrument in their LDAR programs.

To reduce variability attributed to screening instrument, minimum specifications (Table II-9) were established for all instruments used in screening including:

- Model type,
- Minimum instrument accuracy,
- Minimum instrument repeatability,
- Minimum detection limit,
- Minimum instrument resolution
- Instrument range,
- Instrument sampling flow rate
- Instrument response time
- Instrument calibration gas specifications, and
- Instrument probe specifications (diameters, length).

Table II-9. Specifications for Equipment Leak Screening Device

Parameter	Specification
Model Type	Flame Ionization Detector (FID)
Accuracy	± 10 percent of reading or ± 1.0 ppmv, whichever is greater from 1.0 to 10,000 ppmv
Repeatability	2 percent at 500 ppmv of methane
Minimum Detection Limit	0.5 ppmv of methane
Resolution	0.1 ppmv
Range	0 – 30,000 ppmv (methane)
Flow Rate	1 Liter/minute, nominal at sample probe inlet
Response Time	< 3.5 seconds for 90 percent of final value, using 10,000 ppmv of methane
Calibration Gas	Methane
Calibration Gas Concentrations	• Zero air (no more 0.2 ppmv hydrocarbons) • 10 ppmv (± 2 percent) • 100 ppmv (± 2 percent) • 500 ppmv (± 2 percent) • 3,000 ppmv (± 2 percent) • 10,000 ppmv (± 2 percent)
Response Factors (to methane)	Same as Thermo Fisher Scientific TVA2020 Toxic Vapor Analyzer
Probe Outer Diameter	3/16 inch
Probe Inner Diameter	1/8 inch
Probe Length	12 inches for standard probe, 16 inches for enhanced probe
Probe Hose Inner Diameter	1/8 inch
Probe Hose Length	80 inches for standard probes, 88 inches for enhanced probes (in both cases, length is from beginning of the hose to the end of the probe tip)

Instrument Performance

Screening instruments were calibrated prior to each monitoring session using six calibration gases with specified hydrocarbon (methane) concentrations. After calibrating, the instrument measurement to each calibration gas was recorded in standardized forms to use as a comparison of instrument performance after a monitoring session.

To improve the accuracy of the calibration, the standard technique of using calibration gas filled Tedlar bags for calibration was prohibited. Instead, instruments were calibrated directly from calibration gas cylinders equipped with demand flow regulators or through use of a multi-instrument calibrator.

At the end of each monitoring session, each screening instrument was challenged three times against each calibration gas standard with the resulting measurement recorded for each challenge. The difference between the average of the three instrument measurements after monitoring to a calibration gas and the instrument measurement after calibration was defined as the instrument "drift". The instrument drift was calculated by dividing the average of the three instrument readings by the instrument reading after calibration (prior to the monitoring session) converting to a percentage.

$$\mathrm{Drift}_{\mathrm{Span\ Gas}}\ (\%) = \frac{(\text{Average of three drift test readings})_{\mathrm{Span\ Gas}} - (\text{Post calibration instrument measurement})_{\mathrm{Span\ Gas}}}{(\text{Post calibration instrument measurement})_{\mathrm{Span\ Gas}}} \times 100$$

Table II-10. Example Screening Instrument Drift Test and Drift Results

Calibration Gas Target	Zero	10 ppmv	100 ppmv	500 ppmv	3,000 ppmv	10,000 ppmv
Calibration Gas Value	Zero	9.95	98.4	505	2,980	10,200
Calibration	0.2	10.9	99.4	492	3,065	10,000
Quality Assurance Target		± 25%	± 10%	± 10%	± 10%	± 10%
Drift Test						
Reading # 1	-0.4	8.0	95.0	472.0	3,087	10,100
Reading # 2	-0.1	8.7	92.0	471.0	3,047	10,200
Reading # 3	0.2	8.7	101.0	469.0	3,007	9,400
Average	*-0.1*	*8.5*	*96.0*	*470.7*	*3,047*	*9,900*
Percent Deviation		*-22.3%*	*-3.4%*	*-4.3%*	*-0.6%*	*-1.0%*

To reduce the likelihood of an instrument undergoing substantial drift, screening personnel were instructed to pre-emptively switch monitoring instruments after a significant measurement, when the instrument took a lengthy period to return to zero after a measurement (due to heavier hydrocarbons in the instrument), or after measuring a series (25 to 50 components) of particularly heavier process streams.

Screening personnel were also instructed to change probe filters whenever there was a large or significant difference in subsequent monitoring readings to prevent a clogged filter from affecting measurement readings. However, specific criteria for identifying when the filter should be changed was not set and a subjective decision made by each screener based on the components that were monitored (e.g., if components had solidified liquids or rust scaling on the monitoring surface).

Screening Technique and Monitoring Time

Apart from how well a particular screening instrument performs (due to design and calibration), the technique used to screen components was deemed most critical to screening results. Previous studies have shown screening distance to directly impact the leak concentration measured. Therefore, if an instrument probe were not placed at the interface, the measurement may be biased low. Although a third-party auditor viewed screening personnel, while monitoring generally, each measurement was not viewed by the auditor as the number of personnel screening outnumbered the number of auditors and screening personnel were not always located in the same vicinity of each other and/or an auditor.

Locating leaks comprised two parts: 1) moving the instrument probe around the entire interface of a leak location (valve stem, pump seal, flange – gasket interface, etc.) to find the location of a maximum leak, and 2) keeping the probe at the location of maximum leak until a maximum leak measurement was taken.

If screening personnel moved an instrument probe too quickly around a component leak interface, the instrument may not register a leak and results would be biased low. If personnel did not keep the instrument probe at the location of maximum leak for a sufficient time, the instrument would not measure the correct value and results would be biased low. However, the reverse (spending more time than necessary to identify and record the maximum leak concentration) would not bias results high.

A minimum screening time of four seconds per inch of component surface monitored was implemented for finding the location of a maximum leak. Once the location was found, screening instruments were to be held for at least three times the instrument response time at that location. However, the instrument response times varied by stream material.

The screening instruments were calibrated using various concentrations of methane gas. Flame ionization detectors, like the TVA 2020, respond quickly to methane as it is a low molecular gas. As such, the instrument response time to methane gas is typically less than a few seconds. U.S. EPA Method 21 requires that instruments used for screening have a response time of less than 30 seconds. However, this method was promulgated for use in screening gas and light liquid hydrocarbons.

Pre-Study preparatory work and field experience indicated that the performance of the FID instrument to heavier hydrocarbon streams to differ significantly in some cases. Instruments took longer to identify a leak, longer to reach maximum leak reading, and longer to return to background levels once a probe was removed from a source of a leak.

As screening instruments were to be calibrated with methane and the instrument response to longer chain hydrocarbons was not readily known, an attempt was made to understand and quantify the TVA 2020 instrument response and clear times to various hydrocarbons materials.

In the preliminary stages of the Study (before screening began at the pilot refinery), the Air District obtained five samples of heavy liquids (four samples of different grades of gas oil and one sample of residual oil) prepared and provided by Refinery B taken during their daily operating rounds. These samples were heated under a fume hood to three different temperatures while two TVA 2020 instruments were used to take screening measurements and the instrument response time (time it took to read 90 percent of the maximum value) and instrument clear time (time it took the instrument to drop below 2.5 ppmv after a measurement) of each instrument was measured.

***Table II-11**. Screening Instrument Response Times to Different Materials by Material Temperature*

	Screening Instrument Response Times by Material Temperatures (Maximum Screening Measurement)					
	50 Degrees Celsius		75 Degrees Celsius		100 Degrees Celsius	
Material	Instrument 1	Instrument 2	Instrument 1	Instrument 2	Instrument 1	Instrument 2
Residual	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)
Vacuum Tower Light Gas Oil	2 minutes (27.8 ppmv)	2 minutes (21.0 ppmv)	3 minutes (82.5 ppmv)	3 minutes (64 ppmv)	3 minutes (182 ppmv)	3.5 minutes (184 ppmv)
Vacuum Tower Heavy Gas Oil	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)
Cracked Gas Oil (Side Cut 1)	1 minute (9.2 ppmv)	1 minute (3.1 ppmv)	1 minute (20.0 ppmv)	1 minute (11.3 ppmv)	5 minutes (44.2 ppmv)	4 minutes (33.6 ppmv)
Cracked Gas Oil (Side Cut 2)	N/A (1)	N/A (1)	N/A (1)	N/A (1)	2 minutes (18.2 ppmv)	2 minutes (14.7 ppmv)

Note:
1. There was no instrument response to heated material and an instrument response time could not be measured.

Table II-12. Screening Instrument Clear Times to Different Materials by Material Temperature

Material	Screening Instrument Clear Times by Material Temperatures 50 Degrees Celsius		75 Degrees Celsius		100 Degrees Celsius	
	Instrument 1	Instrument 2	Instrument 1	Instrument 2	Instrument 1	Instrument 2
Residual	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)
Vacuum Tower Light Gas Oil	4 minutes	3 minutes	11 minutes	10 minutes	31 minutes	30 minutes
Vacuum Tower Heavy Gas Oil	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)	N/A (1)
Cracked Gas Oil (Side Cut 1)	< 1 minute	< 1 minute	< 1minute	< 1 minute	11 minutes	9 minutes
Cracked Gas Oil (Side Cut 2)	N/A (1)	N/A (1)	N/A (1)	N/A (1)	1 minute	1 minute

Note:
1. There was no instrument response to heated material and an instrument response time could not be measured.

The analysis validated the preliminary field experience that instrument response times varied by material and maximum screening value. However, the results indicated that the TVA 2020 may not meet the U.S. EPA Method 21 requirement for instruments to have a response time of less than 30 seconds when screening components in heavy liquid service.

This information was conveyed to all screening personnel in training sessions. Unfortunately, instrument response times for the diversity of heavy liquid streams could not be developed and used during screening as a quality assurance check.

Data Capture and Information Recording

Each of the petroleum refineries utilized an electronic LDAR program where gas and light liquid service components were given unique identifiers and screening measurements are recorded in the field by electronic handheld devices and then monitoring data uploaded to a centralized electronic database.

Such a system was explored for accurately capturing screening data during the Study. However, it was discovered that components had to be pre-programmed into the system with unique identifiers before screening data could be recorded. The Air District explored with several vendors of electronic LDAR programs the possibility of re-programming their software to allow this functionality, but it was deemed cost prohibitive. The Air District then designed, built, and programmed a portable device that worked in conjunction with the cellular phones of Air District screening staff. However, there were practical difficulties (having to removing safety gloves, small screen, etc.) of data entry into a software application on a phone glass surface. The portable handheld devices used in LDAR monitoring typically have large buttons and require a minimal of entry for screening.

Ultimately, manually writing screening measurements on field sheets was selected as the data capture method since physical field data sheets were still required to capture component information (subtype, size, operating temperature, etc.). This introduced transcription and other data entry errors but allowed for more components to be screened in each monitoring period. Some standard abbreviations were developed for use in succinctly capturing information.

II.iv.2. Mass Emissions Sampling

Multiple procedures and methodologies were employed during emissions sampling to reduce potential bias and ensure quality data.

Personnel

To minimize potential bias from sampling technique, the same personnel were used for each sampling team (Air District and third-party contractor). All personnel involved in sampling participated in training sessions prior sampling.

Data/Information Capture

Standardized field data sheets were used to capture component and sampling information including:

- Equipment type
- Equipment subtype
- Line size
- Stream phase (confirm heavy liquid)
- Barometric pressure
- Ambient temperature
- Stream temperature
- Component temperature
- Stream description
- Component Identification
- Unit Identification
- Date
- Bagging Team
- Screening Instrument Identification
- Sample Pump A Identification
- Sample Pump B Identification
- Stream Pressure

Screening Instruments

Following the U.S. EPA Method 21 screening methodology, an FID instrument was used to measure hydrocarbon concentrations of the component leak pre- and post-sampling as well as during sampling.

A Thermo Fisher Scientific TVA1000B was used at the pilot refinery (Refinery A) while a Thermo Fisher Scientific TVA2020 was used at the other refineries.

All FID instruments were calibrated prior to use as well as had a drift test performed (as described in the previous section) after each sampling session.

FID instruments used in mass emissions sampling at the pilot refinery were calibrated at a centralized location in Benicia prior to deployment each sampling day at Refinery A. FID instruments used at all subsequent refineries were calibrated onsite the refinery where sampling was occurring.

The pump flow of each FID instruments was checked for minimal flow rate.

Component Verification

Components selected for sampling were verified by cross-checking the assigned component study identification number and field sheet information against information listed on a physical tag affixed to the component. In some instances, a selected component was not sampled because of accessibility (scaffolding, component configuration, etc.), external component temperature (greater than 400 to 500 degrees Fahrenheit), the leak location could not be found, the magnitude of the leak changed, or a component was taken out of service.

Component Leak Verification

Prior to sampling, an FID instrument was used to identify the location of maximum leak as well as the magnitude of the leak concentration.

Digital Photographs

Sampled components and sampling system were photographed prior to, during, and after sampling.

Sample Lines

Each sample was taken with either new sample lines or cleaned re-used sample lines. All re-used sample lines were flushed of any sample residue overnight and then tested for hydrocarbons prior to sampling. If hydrocarbon concentrations above background were measured, the sample line was flushed briefly and remeasured. If hydrocarbon concentrations above background were still detected, new sample lines were used. A visual inspection of the sampling line was conducted for condensation and possible contamination.

Equipment Calibrations

Sample pumps, dry gas meter, and temperature gauges were calibrated before sampling at the pilot refinery.

Sample Bag Vacuum Check
The pressure of the sample bag was measured, recorded, and a minimum vacuum confirmed for each sample.

Sample Media Leak Checks
A vacuum check of the series connected sampling tubes was performed prior to each sample to confirm the connecting tubing was free of leaks.

Sample Pump Flow Rate

At the beginning of each sampling day prior to sampling and at the end of each sampling day, the sample pump flow rate of each sampling pump was measured with two dedicated series connected sampling media (charcoal tubes) using a MesaLabs Defender 510 Medium Flow portable calibrator.

Sampling Train Leak Checks

Before taking a sample, a leak check of the entire sampling line (sample line inlet to the dry gas meter outlet) was performed with results recorded.

Replicate Samples

Replicate samples (samples taken as close as possible to the same point in time and space) were taken to understand the variability in sampling technique and in case of damage and/or contamination to the primary sample.

Background Samples

Because samples were taking under vacuum, it was possible that ambient concentrations of hydrocarbons could bias sample results. Therefore, background samples were taken with results subtracted from component sample results.

Repeated (Duplicate) Samples

To understand possible temporal variations in mass emissions as well as possible variations by sampling team, a subset of components were selected for repeated sampling.

Sample Train Recovery Test

Before initiating sampling at a refinery and after completion of sampling at a refinery, a sample train recovery test was performed where a specific amount of methane-in-air gas (methane concentration of ~10,000 ppmv) was introduced into the sampling train and collected in a bag where the concentration of methane was measured using an FID instrument. The theoretical emission rate of methane introduced into the system was calculated using the measured concentrations (introduced and bag measured) and gas flow rates and compared to the calculated emission rate as collected in the bag, correcting for pressure and temperature.

Field Matrix Spike

To ascertain the performance of the laboratory methodology on the sample analytes (matrix interference or matrix effect), a subset of selected components had an additional sample taken using sampling media that had known quantities ("spike") of analytes (C_5 to C_{24} compounds) added prior to field deployment.

Trip Blanks

To determine whether sample media or samples may have been contaminated during transport (to and from each site), clean sample media were provided by the laboratory, taken to each sampling location, and maintained in a closed position until analysis after returning to the laboratory.

Quality Assurance Targets

For quality control purposes, quality assurance targets were established prior to sampling in most instances, and a few were established after sampling at the pilot refinery when changes were made in the sampling procedure (see Methodology – Mass Emissions Sampling). These targets are listed in Table II-13 and Table II-14.

***Table II-13**. Quality Assurance Action Items and Minimum Frequency for Mass Emissions Sampling*

Quality Assurance Action	Minimum Frequency
Sampling Train Recovery Test	Beginning and end of each test period
FID Screening Instrument Calibration	Beginning of each test day
FID Screening Instrument Drift Check	End of each test day
Sample Pump Flow Check	Beginning of each test day
Background Samples	At each test location
Spiked Samples	Every five tests
Trip Blank	1 per sample shipment
Duplicate Sampling	1 per refinery

Table II-14. Quality Assurance Targets for Mass Emissions Sampling

Sampling Item	Quality Assurance Item	Quality Assurance Target
Sampling Train	Prior to taking each sample, a sampling train leak check was performed	100 percent
	A sampling train leak check was performed prior (not after) to each sample	100 percent
	Maximum allowable sampling train leak percentage	± 5 percent
	Maximum allowable sampling train leak	0.5 liters per minute
	A sampling train recovery test was performed before and after each sampling period	± 20 percent of theoretical value
Equipment Calibrations	Sampling pump was calibrated prior to sampling	100 percent
	Dry gas meter was calibrated prior to sampling	100 percent
	Temperature gauge used in sampling was calibrated prior to sampling	100 percent
	Each screening instrument used was calibrated prior to a sampling session	
	Each screening instrument used was calibrated using six calibration gases	
Screening Instruments	Each screening instrument was challenged against six calibration gases for three times and the average drift was recorded	
Calibration Gas Standards	All calibration gases used in course of sampling were not expired	100 percent
Screening Instrument Calibration Gas Standards Hydrocarbon Content	Zero air (less than 0.2 ppm hydrocarbons)	± 15 percent
	10 ppmv, methane	± 2 percent
	100 ppmv, methane	± 2 percent
	500 ppmv, methane	± 2 percent
	3,0000 ppmv, methane	± 2 percent
	10,000 ppmv, methane	± 2 percent
Screening Instrument Sample Pump Flow	The internal sampling pump flow rate of each screening instrument was measured and recorded prior to screening.	
	Minimum sampling flow rate of each screening instrument	1.0 liters per minute ± 10 percent
Dry Gas Meter Flow Rate	Minimum dry gas meter flow rate	5.0 liters per minute
Sample Pump Flow Rate	Minimum sample pump flow rate	1.0 liters per minute
Sample Train Flow Rate	Minimum flow rate for samples where two coconut charcoal tubes in series was used	1.0 liters per minute
	Minimum flow rate for samples where a XAD-2 tube was used	0.75 liters per minute
Sample Volume	Minimum total sample volume	12 liters
Sample Media	XAD-2 resin tubes (SKC catalogue number 226-30-06)	
	Coconut charcoal tubes (SKC catalogue number 226-16)	
Sample Bag Vacuum	Minimum bag vacuum	0.001 – 0.1 inches H_2O

Sampling Item	Quality Assurance Item	Quality Assurance Target
Sample Lines	Sample lines were flushed or cleaned and tested for hydrocarbons with a screening instrument before reuse	100 percent
Training	All personnel involved in screening attended a preliminary training to understand the sampling protocol	100 percent
Background Samples	Minimum number of background samples were taken at each petroleum refinery	2
Repeated Sampling	Minimum number of background samples were taken at each petroleum refinery	1
Duplicate Sampling	A primary and replicate sample was taken for each selected component	100 percent
Standardized Field Data Forms	Standardized forms or field sheets were used to capture sampling information	100 percent
Sample Spike Recoveries	Minimum number of spike recovery studies as a percentage of total sampled components	15 percent
	Allowable difference in spike recovery	± 20 percent recovery
Digital Photograph	All sampled components were digitally photographed before, during, and after sampling	100 percent
Leak Verification	Prior to taking a sample, each sample component was screened using a TVA-2020 (or equivalent) and the maximum screening value was recorded.	100 percent

II.iv.3. Laboratory

Including those outlined in U.S. EPA Method 18, additional quality assurance and quality control procedures were employed during laboratory analysis of samples.

Laboratory

The same laboratory (Enthalpy Analytical LLC in Durham, North Carolina) was used to analyze all samples.

Sample Condition and Access

All samples were transported to the laboratory with ice packs to maintain temperatures below the maximum allowed by the method. A chain of custody record was used to document possession and all transfers of each sample between the field and laboratory. Once received by the laboratory, samples were kept under lock with access only to authorized laboratory personnel prior to, during, and after analysis.

Second Sampling Tube

Every sample was taken with two charcoal tubes in series and a select few were taken with a XAD tube in series with the charcoal tubes with the XAD tube closest to the component leak. The second charcoal tube was archived by the laboratory and only analyzed when breakthrough of the first charcoal tube was suspected.

Method Blanks

With each batch of samples, laboratory blanks were prepared and analyzed using the same procedures as each sample to evaluate whether there was contamination arising from the laboratory preparation and/or analytical procedure.

Matrix Spike

Prior to field deployment at a refinery, the laboratory prepared 21 charcoal sampling tubes where a primary stock solution with specific amounts of certain compounds was added to all 21 tubes. Additional amounts of either low, medium, or high quantities were added to seven tubes each (see Table II-15).

Table II-15. *Matrix Spike Compounds and Amounts*

Compound	Primary Stock Spike (µg)	Low Spike Amount (µg)	Medium Spike Amount (µg)	High Spike Amount (µg)
n-Pentane (C_5)	50.4	N/A	N/A	N/A
n-Hexane (C_6)	49.7	N/A	N/A	N/A
n-Heptane (C_7)	49.8	N/A	50.9	170
n-Octane (C_8)	49.6	N/A	105	456
n-Nonane (C_9)	50.0	N/A	303	2,140
n-Decane (C_{10})	50.4	54.4	798	1,706
n-Undecane (C_{11})	50.3	129	1,142	958
n-Dodecane (C_{12})	50.0	103	936	412
n-Tridecane (C_{13})	50.1	150	449	105
n-Tetradecane (C_{14})	50.0	95.1	47.5	N/A
n-Pentadecane (C_{15})	50.3	47.9	N/A	N/A
n-Hexadecane (C_{16})	50.0	N/A	N/A	N/A
n-Heptadecane (C_{17})	49.4	N/A	N/A	N/A
n-Octadecane (C_{18})	50.0	N/A	N/A	N/A
n-Nonadecane (C_{19})	50.1	N/A	N/A	N/A
n-Eicosane (C_{20})	50.0	N/A	N/A	N/A
n-Heneicosane (C_{21})	50.4	N/A	N/A	N/A
n-Docosane (C_{22})	49.9	N/A	N/A	N/A
n-Tricosane (C_{23})	50.1	N/A	N/A	N/A
n-Tetracosane (C_{24})	50.2	N/A	N/A	N/A
Note: "N/A" = not applicable				

Five sample tubes of each spike amount (low, medium, and high) were provided to the sampling team for use in the field. These spiked tubes were used to determine if the sample matrix had an interference or effect on the target analytes (whether anything in the sample interfered with the analysis).

Two tubes of each spike amount were held by the laboratory for use as laboratory control samples.

Laboratory Control Sample

As discussed above, when matrix spikes were prepared for field deployment at one of the petroleum refineries, two spikes were retained for laboratory control samples and kept at the appropriate temperature conditions.

One or more laboratory control samples were prepared and analyzed with each batch of samples to determine that an analyte within a matrix spike may be recovered from the media and were used to assess the performance of the laboratory's analytical system.

Laboratory Duplicate

For every batch of samples analyzed, one sample was chosen to where an additional aliquot of the sample was prepared for testing. The results of the duplicate were then compared to the results of the sample to determine the precision of the laboratory analytical procedures.

Quality Assurance Targets

Quality assurance targets established for quality control associated with laboratory analyses are listed in Table II-16.

Table II-16. Quality Assurance Targets for Laboratory Analyses

Item	Quality Assurance Item	Quality Assurance Target
Laboratory Methodologies	Samples collected using sorbent tubes as well as any collected condensate were analyzed using EPA Method 18	100 percent
	Samples collected using evacuated canisters were analyzed using EPA Method 18, EPA TO-14A, and EPA TO-15.	100 percent
	Samples that contained compounds that were polymeric (high molecular weight), could polymerize before analysis, or had very low vapor pressure at instrument conditions were analyzed to determine whether a method other than EPA Method 18 should be used.	N/A
Target Analytes	Minimum analyte target range for samples taken with an evacuated cannister	C_1 to C_4
	Minimum analyte target range for samples taken with a sorbent tube	C_5 to C_{24}
	Minimum analyte target range for samples where condensate was present.	C_5 to C_{30}
Detector	Where samples were collected on sorbent tubes, gas chromatography (GC) was used (percentage of total such samples)	100 percent
Carbon Number Retention Time Windows	Where samples were collected on sorbent tubes, carbon number retention time windows were established.	100 percent
Quantitation	All peaks within established carbon number retention time windows were quantitated using the response factor of the associated n-alkane.	100 percent
	All late eluting peaks (after C_{24}) were quantitated using the response factor of the last calibrated peak (e.g., C_{25+} using C_{24})	100 percent
Limit of Detection	All samples that had measured values below the limit of detection were reported at the limit of detection (percentage of total such samples)	100 percent
Column Choice	Gas chromatograph column based upon the target analytes and potential constituents within the sample being analyzed.	100 percent
Oven Temperature Ramp	Range and rate of temperature ramping based upon the target analytes and potential constituents within the sample being analyzed.	
Training	All personnel involved in sampling attended a preliminary training to understand sampling protocol (percentage of total such personnel)	100 percent
EPA QA/QC	All quality assurance and quality control measures were followed as prescribed in any applicable EPA analytical or sampling method used.	
Blank Media	Analytes of interest were not identified in analyses of laboratory blanks	100 percent
Laboratory Duplicates	Maximum allowable difference between a sample and a laboratory duplicate	± 10 percent
Laboratory Control Samples	Minimum number of laboratory control samples per refinery	2

II.iv.4. Analysis

Although not as readily apparent as field screening and sampling, data analysis could introduce errors producing bias in results and therefore, required quality assurance and quality control procedures.

Data Entry Errors and Blank Entries

Data collected on various physical, standardized field data sheets (screening, mass emissions sampling, instrument calibrations and drift checks, etc.) was manually entered into electronic spreadsheets for analyses. Manually entry of data created an additional source of error and required the following verifications:

- Background Verification – all spreadsheet entries of background screening measurements that were greater than 5 ppmv were cross-checked against screening field data sheets.
- Leak Verification – all spreadsheet entries of component screening measurements that were greater than 2.5 ppmv (for the pilot refinery) or 25 ppmv (for the other four refineries) were cross-checked against screening field data sheets and digital photographs taken of the component.
- Text entry – all spreadsheet entries of numerical values were inspected for values entered as "text" and converted to numerical values.
- Blank Entries – blank entries in the spreadsheet for multiple parameters were verified as missing from field data sheets. If missing, "Blank" was entered in the electronic spreadsheet. If not missing, value listed in the field data sheet was entered. Parameters checked for blank entries included component size, vibration amount, cyclic vibration, elevation, external component temperature, operating pressure, monitoring start / stop times, background screening measurements, component screening measurements, component screening instrument number, ambient temperature, and windspeed/direction.

Component Classifications

The digital photographs of all components that were digitally photographed were reviewed for component classification.

- Pumps - Only the pump seal of a pump was classified as a pump.
- Valves – If a screening measurement or mass emissions sample did not include the valve stem, the component was not classified a valve but rather a connector.
- Pressure Relief Valves – If the pressure relief valve did not have an opening to atmosphere (either a horn or a weep hole), it was not deemed a pressure relief valve but rather a connector.

The petroleum refineries were surveyed for all entries for pressure relief valves to confirm whether the pressure relief valve had an opening to atmosphere.

Material Classification

The petroleum refineries were asked to confirm stream materials listed in field data sheets as well as to provide generalized process stream categories for each listed material. Components handling materials that were deemed not to meet the definition of "heavy liquid" were excluded from the Study.

Duplicate Entries

All entries using the same measurement identification number was reviewed and cross-checked against field data sheets to determine if the same identification number was used for two (or more) different components or whether the same component was screened multiple times.

Atypical Entries

Atypical entries were cross-checked against field data sheets and confirmed with relevant petroleum refinery.

Missing Quality Assurance Checks / Transcription Errors

Where quality control checks were missing (e.g., missing calibration and drift checks for an instrument listed on a field sheet), reviewed field data sheets, 3rd-party auditor forms, calibration gas and drift field sheets, and other information to determine if an obvious transcription error occurred.

Missing Components / Extrapolation

Lab results of lighter organic compounds were extrapolated to the entire sample population when the concentration of lighter organic compounds exceeded five percent of the total concentration.

III. Results

The results of component screening, mass emissions sampling, statistical analyses, and quality control activities are summarized in this section. A discussion of these results is provided in Section IV Discussion.

i. Components

III.i.1. Petroleum Refinery

All five petroleum refineries were included in the Study. Between 1,000 to 2,000 components per petroleum refinery and between 6,000 to 10,000 components at all five refineries were targeted for inclusion within the Study. The total number of components and the total number of components with screening measurements by refinery are shown in Table III-1.

Table III-1. Number of Study Components by Petroleum Refinery

Petroleum Refinery	Number of Components	Number of Components with Measurements
A	2,076	2,069
B	2,084	2,081
C	2,189	2,186
D	2,412	2,293
E	2,195	2,194
Total	10,956	10,823

Both targets (number of components per petroleum refinery and total number across all five petroleum refineries) were met.

III.i.2. Process Units

As each petroleum refinery had their own naming convention for their process units, selected process units were categorized by general process unit category (see Table III-2. Petroleum Refinery Process Units Included in the Study for general process units included in the Study).

Table III-2. Petroleum Refinery Process Units Included in the Study

	Refinery				
Process Unit Category	A	B	C	D	E
Crude Unit	X	X	X	X	X
Fluidized Catalytic Cracking Unit	X		X	X	X
Hydrocracking	X	X	X	X	X
Hydrotreating					
Diesel	X	X	X	X	
Jet			X		
Gas Oil				X	
Naphtha		X			
Coker					
Delayed Coker	X	X		X	
Fluid Coker					X
Flexicoker				X	

Process Unit Category	A	B	Refinery C	D	E

Utilities	2	2
Vacuum Distillation Unit	13	13
Total	10,956	10,823

III.i.3. Component Types and Sub-Types

Study components were classified by four types (pump seals, connectors, valves, or pressure relief device). The number of Study components by component type are presented in Table III-5.

Table III-5. Number of Study Components by Component Type

Component Type	Number of Entries	Number of Entries with Measurements
Pump Seals	797	734
Connectors	4,779	4,710
Valves	5,350	5,349
Pressure Relief Devices	30	30
Total	10,956	10,823

Component subtype categories were identified for connectors, valves, and pressure relief devices. Because of the number and diversity of component subtypes, a standardized listing of subtypes was not identified or provided to field personnel and subtype categorizations were left to the field personnel completing the standardized field data sheets. Identification and categorization of a component subtype depended upon the familiarity and knowledge of field personnel.

The number of Study components by component subtype are listed in Table III-6.

Table III-6. Distribution of Study Components by Component Type and Component Subtype

Component Type	General Component Subtype	Number of Entries	Number of Entries with Measurements
Pumps	All	797	734
Connectors	Coupling	13	13
	Elbow	52	52
	End Cap	12	12
	Flange	1,501	1,499
	Gate	15	15
	Hatch	13	13
	Manway	9	9
	Other	3	3

	Unknown	298	298
Pressure Relief Devices	Pressure Relief Valve	6	6
	Rupture Disc	1	1
	Safety Valve	9	9
	Unknown	14	14
	Total	10,956	10,823

III.i.4. Materials

There were several hundred unique designations of process stream materials identified by field personnel in completed field data sheets. These names were identified either on process line piping or pumps (via stenciled lettering), from process flow diagrams, or from piping & instrumentation diagrams.

For comparison and analysis purposes, these streams were categorized into general streams with input from the petroleum refineries.

The process stream for approximately 300 components could not be categorized due to either blank entries, unknown abbreviations, or other reasons. These components were categorized as “Unknown”.

The process stream for another several hundred components were categorized as “Other”.

Table III-7. Distribution of Study Components by General Stream Service

General Stream Service	Number of Components	Number with Measurements
Amine	153	153
Asphalt	349	349
Asphalt/Resid	90	90
Atmospheric Tower Bottoms	57	57
Cetane Improver	36	36
Coke	22	22

Unknown	290	290
Vacuum Gas Oil	17	17
Vacuum Tower Bottoms	287	287
Total	10,956	10,823

III.i.5. Other

Other than component type, subtype, process unit, and process stream; additional variables were investigated to determine if there were a correlation with measured leak rates.

Component Size

Most components screened were less than one inch in diameter as shown in **Figure III.1** and **Table III-8**. This was not by design but rather a function of the disparity in the number of such components on process lines as compared to larger process lines.

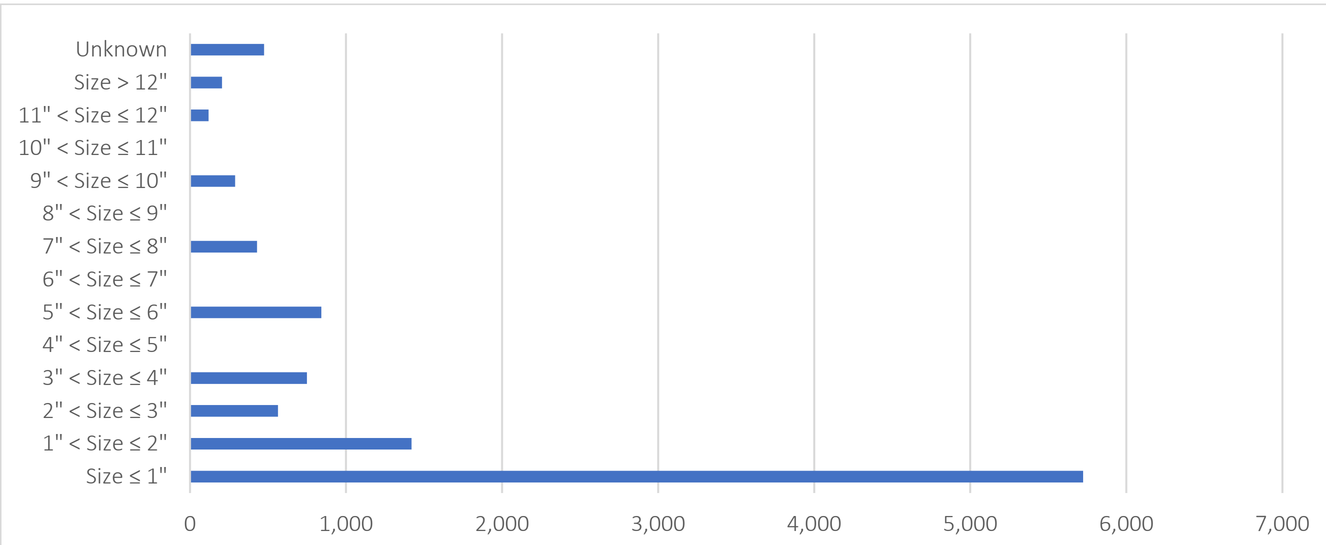

Figure III.1. Count of Study Components Screened by Component Size (Process Line Diameter)

Table III-8. Distribution of Study Components Screened by Component Size

Size (inches)	Number Screened	Number Screened as Percentage of Total Screened (%)
Size ≤ 1"	5,723	52.9
1" < Size ≤ 2"	1,420	13.1
2" < Size ≤ 3"	564	5.2
3" < Size ≤ 4"	748	6.9
4" < Size ≤ 5"	5	0.05
5" < Size ≤ 6"	842	7.8
6" < Size ≤ 7"	0	0
7" < Size ≤ 8"	430	4.0
8" < Size ≤ 9"	3	0.03
9" < Size ≤ 10"	289	2.7
10" < Size ≤ 11"	0	0
11" < Size ≤ 12"	119	1.1
Size > 12"	205	1.9
Unknown	475	4.4
Total	**10,823**	**100**

Component Operating Pressure

Component operating temperature was difficult to ascertain as not every process line had a readily available pressure gauge or pressure indicator to view. In some cases where a pressure indicator was not present, field personnel were able to obtain this information from process unit operators. However, the operating pressure of approximately 28 percent of components with screening measurements could not be identified (Figure III.2, Table III-9).

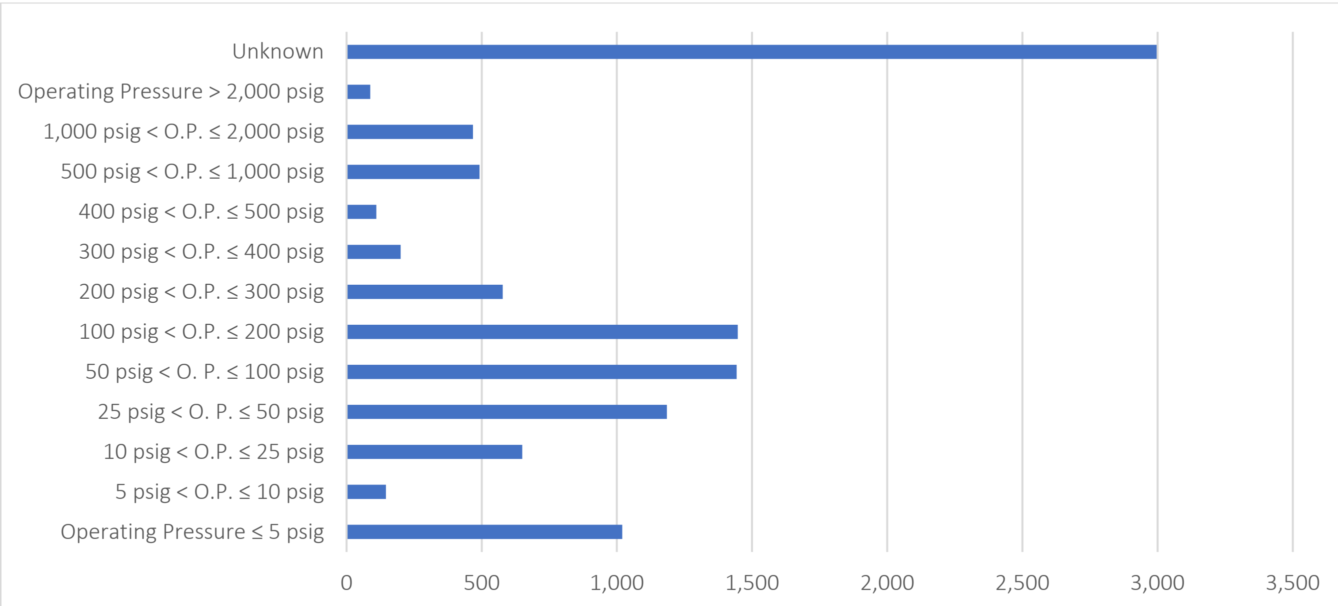

Figure III.2. Count of Study Components Screened by Component Operating Pressure

Table III-9. Distribution of Study Components Screened by Component Operating Pressure

Operating Pressure (psig)	Number Screened	Number Screened as Percentage of Total Screened (%)
Operating Pressure ≤ 5 psig	1,020	9.4
5 psig < Operating Pressure ≤ 10 psig	146	1.3
10 psig < Operating Pressure ≤ 25 psig	650	6.0
25 psig < Operating Pressure ≤ 50 psig	1,184	10.9
50 psig < Operating Pressure ≤ 100 psig	1,443	13.3
100 psig < Operating Pressure ≤ 200 psig	1,447	13.4
200 psig < Operating Pressure ≤ 300 psig	578	5.3
300 psig < Operating Pressure ≤ 400 psig	200	1.8
400 psig < Operating Pressure ≤ 500 psig	110	1.0
500 psig < Operating Pressure ≤ 1,000 psig	492	4.5
1,000 psig < Operating Pressure ≤ 2,000 psig	468	4.3
Operating Pressure > 2,000 psig	88	0.8
Unknown	2,997	27.7
Total	10,823	100

Component External Temperature

In lieu of obtaining process material operating temperature that was not readily available (there were less temperature indicators than pressure indicators present in the field), a component's external temperature was obtained using a portable infrared temperature instrument. Care was taken to select a location on the component that was closest to the process fluid. Although external temperatures would be expected to be lower than the process fluid due to heat transfer (conduction, convection, and radiation), the external temperature should still be a valid surrogate. Most components screened (Figure III.3, Table III-10) had external temperatures above ambient temperatures (greater than 100 degrees Fahrenheit) as would be expected with heavy liquid streams. However, a significant portion (approximately 41 percent) had external temperatures at or near ambient temperature.

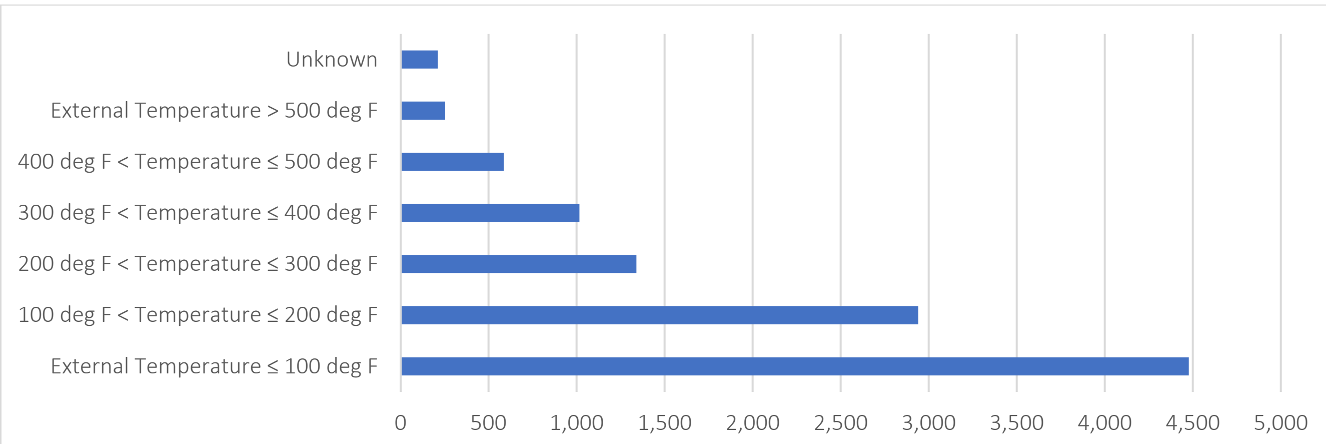

Figure III.3. Count of Study Components Screened by Component External Temperature

Table III-10. Distribution of Study Components Screened by Component External Temperature

External Temperature (Degrees Fahrenheit)	Number Screened	Number Screened as Percentage of Total Screened (%)
External Temperature ≤ 100 deg F	4,476	41.4

Component Vibration

During training and listed on field data sheets, field screening personnel were instructed to identify if a component were vibrating and if so, to make a subjective determination on the degree of vibration. Personnel were provided three options: none, low, or high. However, some field personnel entered "medium" on field data sheets, and these were left as is.

A more objective measurement of vibration could have been obtained using a portable vibration monitor with pre-established values for "none", "low", and "high". However, there were several concerns with this approach:

- Safety concerns: a portable vibration monitor would require being in closer contact with a component than either the screening instrument probe or infrared temperature instrument,
- Personnel: additional personnel may have been needed for vibration monitoring. Component screening already required two personnel, one to screen and one to record information and take temperature measurements, and
- Timing: use of a portable vibration monitor was likely to significantly extend the amount of time spent screening.

Because of the above reasons, more precise vibration monitoring was not conducted. Most screened components were found to have low or no vibration (Figure III.4, Table III-11).

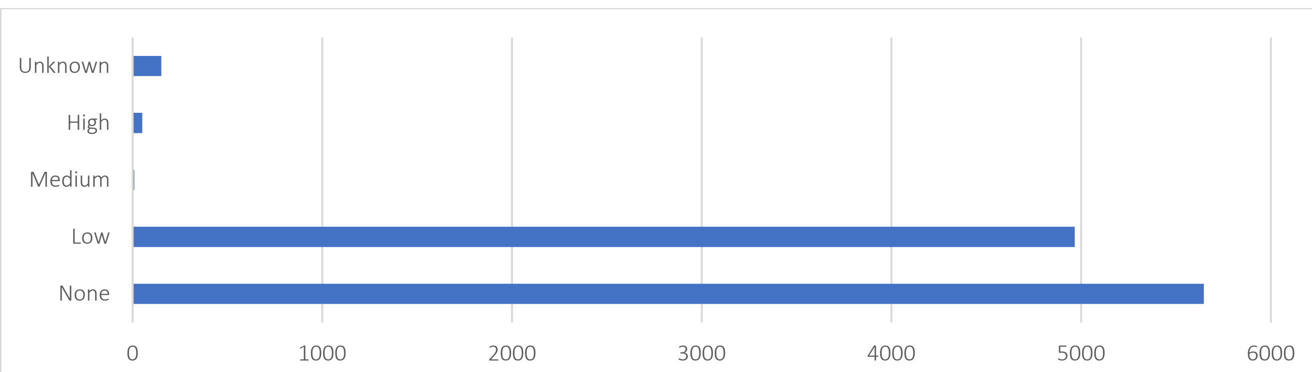

Figure III.4. *Count of Study Components Screened by Component Vibration Amount*

Table III-11*. Distribution of Study Components Screened by Component Vibration Amount*

Vibration Amount	Number Screened	Number Screened as Percentage of Total Screened (%)
None	5,646	52.2
Low	4,966	45.9
Medium	9	0.1
High	51	0.5
Unknown	151	1.4
Total	10,823	100

Component Cyclic Vibration

Separate from whether a component was vibrating at the time of screening, field personnel were instructed to determine whether a component experienced or was expected to experience cyclic vibration. Field personnel were provided the example of components located on a pump that periodically operated (frequent starts and stops) as well as on reactors or vessels that underwent periodic operation cycles such as a coke drum. The experience of field personnel was relied upon to make this determination as pre-determining from submitted drawings was not practical and/or difficult to accomplish.

Less than one percent of screened components was identified as subject to cyclic vibration as shown in Figure III.5 and Table III-12.

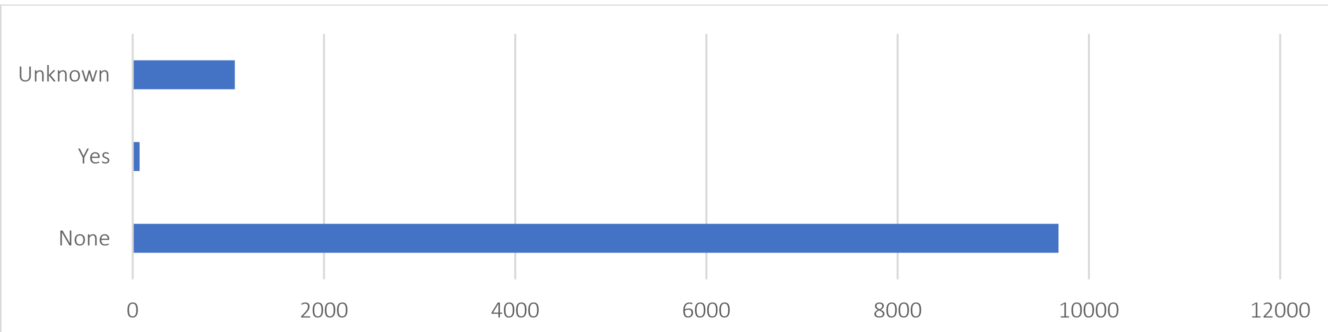

Figure III.5. *Count of Study Components Screened by Component Cyclic Vibration*

Table III-12. Distribution of Study Components Screened by Component Cyclic Vibration

Cyclic Vibration	Number Screened	Number Screened as Percentage of Total Screened (%)
None	9,681	89.4
Yes	73	0.7
Unknown	1,069	9.9
Total	**10,823**	**100**

Component Elevation / Location

Petroleum refinery personnel (process unit operators, area supervisors, maintenance, etc.) conduct periodic (once a shift, daily, weekly, monthly, etc.) visual inspections of equipment (e.g., check instrument gauges, the functionality of rotating equipment). However, not all equipment (such as the top of a column) may be visually checked regularly.

Leaks from components that are not included in a regular leak monitoring program such as heavy liquid service may or may not be discovered by audio, olfactory, or visual means depending upon how frequent refinery personnel are in proximity to such equipment. As such, the location of a component may influence found leak rates.

Ideally, the locations of components that are routinely inspected, either through periodic rounds or in LDAR monitoring, would be mapped and compared to the location of Study components. However, this would entail a significant amount of time, effort, and ultimately may not be possible.

Rather, four options were provided to screening personnel and listed on field data sheets: “ground”, “platform”, “top of column”, and “other”.

A deliberate intent was made to incorporate process lines at various elevations to ascertain the potential impact of component location / elevation. However, most screened components (Figure III.6, Table III-13) were found at ground level.

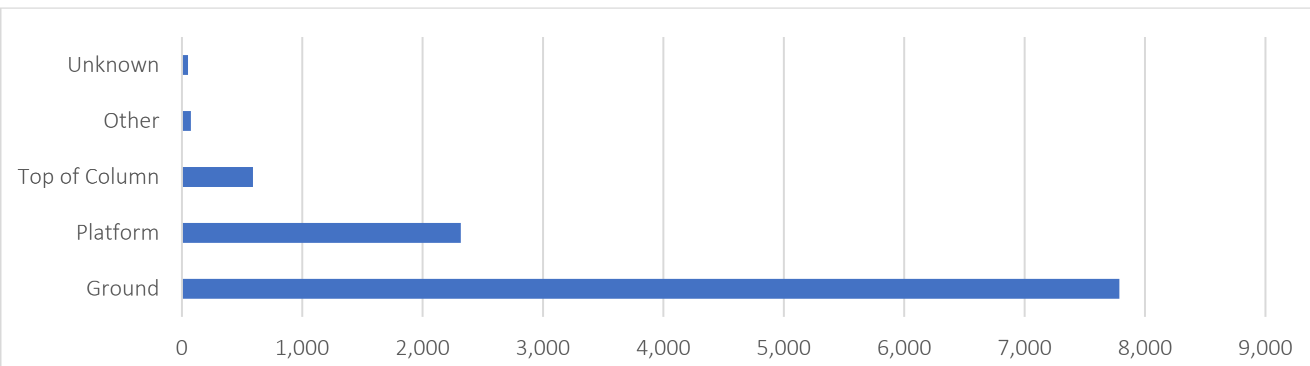

***Figure III.6**. Count of Study Components Screened by Component Elevation / Location*

***Table III-13**. Distribution of Study Components Screened by Component Elevation / Location*

Component Location	Number Screened	Number Screened as Percentage of Total Screened (%)
Ground	7,786	71.9
Platform	2,318	21.4
Top of Column	591	5.5
Other	76	0.7
Unknown	52	0.5
Total	**10,823**	**100**

Component Monitoring Time / Pace

The amount of time screening a component may influence whether a leak was identified, the location of a maximum leak (where a component leaked in more than location), as well as the magnitude of the leak measured. More than half of the components were screened at one minute or less (Figure III.7, Table III-14).

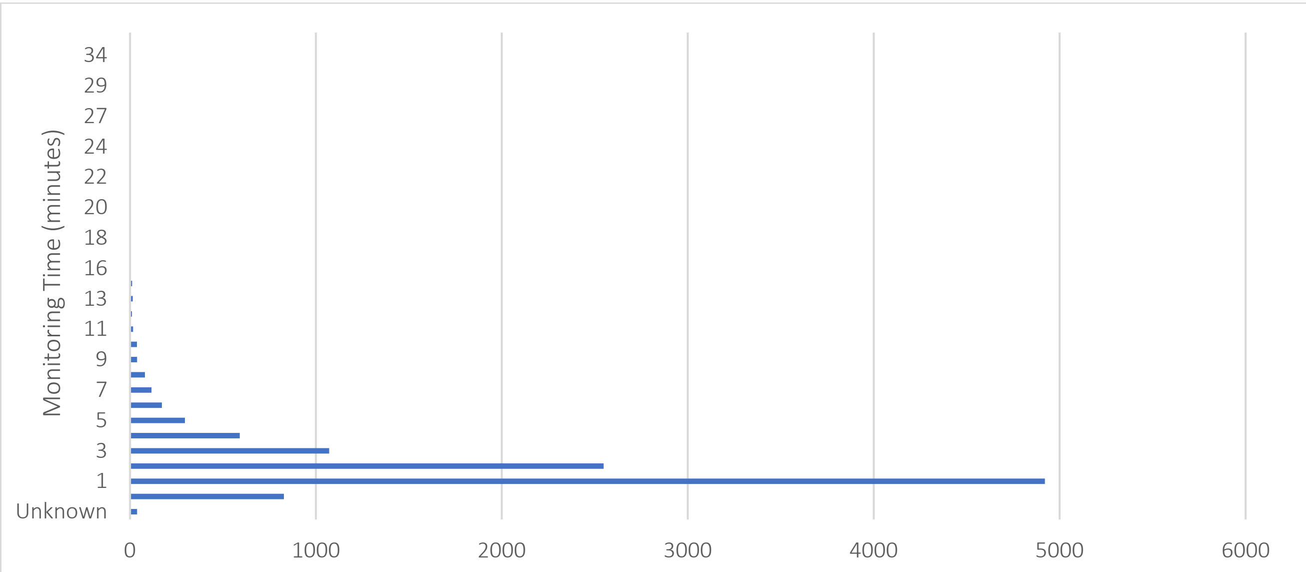

Figure III.7. Count of Study Components Screened by Component Monitoring Time

Table III-14. Distribution of Study Components Screened by Component Monitoring Time

Screening Time (minutes)	Number Screened	Number Screened as Percentage of Total Screened (%)
Unknown	30	0.3
≤ 1	5,749	53.1
2	2,547	23.5
3	1,072	9.9
4	591	5.5
5	296	2.7
6	172	1.6
7	116	1.1

21 – 25	7	0.1
26 – 30	5	0.05
31 – 36	2	0.02
Total	10,823	100

However, as shown in Table III-8, most screened components were small (process line diameter less than one inch). Smaller components should have less potential leak interfaces that require less time to screen as compared to larger components, all else being equal. To account for this, an estimated monitoring pace for each component was derived using the following equation:

$$\text{Pace} = \left[\frac{\text{Measurement Time}}{\left(2\times\pi\times\left(\frac{\text{Process line diameter}}{2}\right)\right)}\right] \times \left[\frac{60 \text{ seconds}}{1 \text{ minute}}\right] \qquad \text{[III-1]}$$

where:

Pace	= Component monitoring pace (seconds/inch)
Measurement Time	= Component measurement time (minutes)
Process line diameter	= Diameter of process line associated with the component (inches)

This equation assumes that a component's total potential leak interface requiring to be screened is equal to the circumference of the component (line size). For flanges and pump seals, this assumption should be reasonably approximate. However, this assumption may or may not be approximate for valves depending upon the valve type and whether a valve bonnet flange was bolted (potential leak interface) or welded (not screened). The measurement time includes both the time to identify the location of maximum leak as well as the time spent measuring the leak at that location. Using this equation, an estimated monitoring pace was derived for each component with totals counts and counts by refinery shown in Figure III.8, Figure III.9, Table III-15, and Table III-16.

ii. Screening

Field screening began at the pilot refinery (Refinery A) in November 2016 and was completed at the last refinery (Refinery E) in May 2018. The number of actual screening days totaled 95. Field screening was interrupted several times for a variety of reasons.

There was an approximately four-month interval between the end of screening at Refinery A and the beginning of screening at Refinery B where preliminary observations were used to modify the study methodology.

There was an approximately eight-month period in the middle of screening at Refinery B because of a safety stand down that necessitated a change in screening methodology where the Air District no longer conducted field screening but rather petroleum refinery personnel or petroleum refinery contractors. The switch in personnel required the Air District to contract with third-party auditors to oversee screening done by the petroleum refinery personnel and/or their contractors.

III.ii.1. Field Observations

Screening personnel identified numerous differences when screening components in heavy liquid for the Study as compared to screening components in gas or light liquid service, which are routinely screened for regulatory compliance. Some of the differences that were noted included:

- Slower instrument response to leaks, which necessitated longer screening times to reach the peak screening value and a slower monitoring pace,
- Longer times for instruments to return to background concentration levels after measuring a leak,
- Higher component temperatures (some over 900 degrees Fahrenheit), causing safety concerns of inadvertently touching an uninsulated surface as well as heat stress / exhaustion from prolonged exposure to screening of hot components,
- Components under insulation preventing and or limiting access,
- Pressure relief valves venting to atmosphere were minimal with most venting to process or flare relief systems,
- More likely to encounter components with solidified or liquid material from previous or existing liquid leaks,
- Because of the age of insulation, there was a concern regarding potential asbestos exposure (an encounter with crumbling insulation caused screening to stop until the material was sampled), and
- Certain pumps handling heavier, more viscous process streams utilized a hot oil or steam quenching system where billowing vapor / steam prevented screening at the required screening distance and/or caused screening instruments to malfunction.

One pump at Refinery A that had a steam injection quench system was found to leak at 760 ppmv at a foot or more distance with liquid hydrocarbons dripping and pooling at the base of the pump. This pump had steam /

vapor billowing around the seal that prevented monitoring closer to the seal. Because of the magnitude of the leak a distance and the liquid leaks, this pump was viewed as having a leak greater than 10,000 ppmv.

In addition to differences with screening of heavy liquid service components, the following observations were also found:

- Some pumps at each of the five refineries could not be screened at the required distance because of grates, guards, or metal plates surrounding the rotating shaft,
- Some components in heavy liquid service were included in a petroleum refinery's leak detection and repair program and were being routinely monitored, and
- Some pumps had multiple seals. In these cases, separate entries were made for each seal.

There were various reasons for why components in heavy liquid service were included in a petroleum refinery's leak detection and repair (LDAR) program. In some instances, these components were required to do so because of a Best Available Control Technology determination. In other cases, components switched between light liquid and heavy liquid service dependent upon the operation. And in others, it was the result of a corporate policy regarding a certain class or stream service.

At Refinery A, pre-selected process lines that had components found to be included in an LDAR program were screened if they were handling a heavy liquid process stream.

As the intention of routine monitoring within an LDAR program is to find and repair leaks, components in an LDAR program are likely to emit less than those not in such a program. Thus, emissions from such components may underestimate (bias low) average emissions from components not monitored. Consequently, after Refinery A, it was determined to exclude such components from screening at the four other refineries.

III.ii.2. Measurements

With each component screening measurement, a screening measurement of the ambient background near the component was taken as well. To account for background influences, a component's background screening measurement was subtracted from a component's screening measurement to produce a net measurement ("above background"). Although screening instruments had the capability of and did show concentrations greater than 10,000 ppmv, because instruments were not calibrated with a standard gas above 10,000 ppmv, the maximum screening value shown in results is 10,000 ppmv. However, there were instances where leaks caused an instrument to "flame out". This typically occurs with leaks of 100,000 ppmv or more. Components with leaks above 10,000 ppmv are listed as "> 10,000 ppmv".

The results of these net measurements by process units, component types and subtypes, stream materials, and other categories are presented in the following sections.

III.ii.2.1. Process Units

Net screening measurements by screening general process unit or area category and concentration range are present in both tabular (Table III-17) and graphical forms (Figure III.10).

Figure III.10. Distribution of Screening Measurements (above background) by General Process Unit / Area Category

III.ii.2.2. Component Types and Sub-Types

Every component that was screened was categorized by component type. Screening results for four categories of component type are presented: pump seals, connectors, valves, and pressure relief devices. However, not every pressure relief device was a pressure relief valve that vented to atmosphere.

The distribution of net screening measurements by screening range and component type is shown in Table III-18 as well as plotted (Figure III.11, Figure III.12, Figure III.13, Figure III.14, Figure III.15, Figure III.16, Figure III.17) with frequency on the original and log scale.

Table III-18. Number of Screening Measurements by Component Type and Screening Measurement Range (Above Background)

Component Subtypes

In addition to component type, an attempt was made to document and classify component subtypes. However, not all screened components had entries for component subtype on completed field data sheets or an abbreviation was used that could not be deciphered. Most pumps were found to have pump type missing. Therefore, results by pump type are not presented.

The number of component subtypes varied by component type:

- connectors: 19 subtypes,
- valves: 17 subtypes, and
- pressure relief devices: 4 subtypes.

The distribution of net screening measurements by count and percentage of totals and by component subtype for connectors, valves, and pressure relief devices are presented in the following tables and figures.

Table III-19*. Connector Subtype Counts by Net Screening Measurement*

Figure III.20. Count of Screening Measurements by Pressure Relief Device Subtype and Screening Measurement Range (Above Background)

III.ii.2.3. Materials

There were over 300 unique entries for stream material entered in screening field sheets. Most of these could be readily categorized into general process streams. Some required consultation with the petroleum refineries. However, not all could be categorized because of blank entries, difficulty interpreting field sheet entries, and/or mixed streams not readily classified.

Although not by design, components in some process streams were screened more than others dependent upon the process units selected for inclusion, process lines, and number of components attached to those process lines.

Table III-25. Distribution of Screening Measurements by General Stream Service and Net Screening Measurement

Figure III.21. *Count of Screening Measurements by General Process Stream Material and Net Screening Measurement Range*

III.ii.2.4. Other

Component Size

Screened components varied in size from ¼ inch in diameter to 100 inches in diameter. There were 45 unique entries for component size. Screened components were grouped into one of 14 size categories. Approximately four percent (475 components) of screened components did not have entries for size on field data sheets. Of these, 97 percent (459 components) were either pump seals or pump housing.

The distribution of component counts by size (process line diameter) and screening net measurement is shown in Table III-26.

The percentage of components in each size category by screening net measurement range are shown in Table III-27.

Component Operating Pressure

Operating pressure of screened components noted on field data sheets varied between -27 psig to 3,900 psig and there were 245 unique entries. The operating pressure of approximately 10 percent (1,100 components) of screened components was unknown.

Screened components were grouped into one of the 13 operating pressure categories:

- Operating pressure ≤ 5 psig,
- 5 psig < Operating Pressure ≤ 10 psig,
- 10 psig < Operating Pressure ≤ 25 psig,
- 25 psig < Operating Pressure ≤ 50 psig,
- 100 psig < Operating Pressure ≤ 200 psig,
- 300 psig < Operating Pressure ≤ 400 psig,
- 500 psig < Operating Pressure ≤ 1,000 psig,
- 1,000 psig < Operating Pressure ≤ 2,000 psig,
- Operating Pressure > 2,000 psig, and
- Unknown.

The distribution of component counts by these categories is shown in Table III-28.

Within each category, the percentages of components by screening net measurement are shown in Table III-29.

Table III-28. Distribution of Screened Components by Operating Pressure and Screening Net Measurement

1. Does not Include component A-477 (pump seal measuring 760 ppmv at distance with liquid hydrocarbons, treated as over 10,000 ppmv leak)
2. Includes component A-477 (pump seal measuring 760 ppmv at distance with liquid hydrocarbons, treated as over 10,000 ppmv leak)

Component External Temperature

There were 1,482 unique entries for “temperature” listed on screening field data sheets. In some instances, a range (“150 – 250”, “500 – 600”, etc.) or minimum threshold (“>300”) was listed. These were classified as unknown and grouped with entries where an entry was left blank or value not provided (e.g., “Insulated”).

Temperature entries varied from 0 degrees Fahrenheit (an amine pump) to 920 degrees Fahrenheit (crude unit components handling light vacuum gas oil).

Screened components were sorted into one of seven temperature categories:

- External Temperature ≤ 100 deg F,
- 100 deg F < Temperature ≤ 200 deg F,
- 300 deg F < Temperature ≤ 400 deg F,
- 400 deg F < Temperature ≤ 500 deg F,
- External Temperature > 500 deg F, and
- Unknown.

An increment of 100 degrees Fahrenheit was chosen as the threshold for delineating categories because smaller differences in external temperature could be attributed to heat transfer differences rather than stream operating temperature differences. Two components with a difference in external temperatures of 100 degrees or more is more likely to be attributed to a difference in stream operating temperature rather than simply a result in differences in heat transfer.

The distribution of component counts by screening net measurement within each of these categories is provided in Table III-30.

Within each category, the percentages of total components within each screening net measurement range are listed in Table III-31.

Table III-30. Distribution of Screened Components by External Temperature and Screening Net Measurement

External Temperature (Degrees Fahrenheit)	Component Counts by Screening Net Measurement (Maximum Measurement - Background) (ppmv)

2. Includes component A-477 (pump seal measuring 760 ppmv at distance with liquid hydrocarbons, treated as over 10,000 ppmv leak)

Component Vibration

Approximately 46 percent of screened components were identified as vibrating at the time of screening. Of these components, 98.8 percent were identified as vibrating at a low amount, 1.0 percent were identified as vibrating at a high amount, and the remainder at a medium level. The vibration amount of 1.4 percent of the screened components was unknown.

The distribution of screened components by identified vibration amount and screening net measurement as well as the percentage of components within each category by screening net measurement are shown in the following tables (Table III-32, Table III-33).

Table III-32. *Distribution of Screened Components by Vibration Amount and Screening Net Measurement*

Component Cyclic Vibration

Less than 0.7 percent of screened components were identified by screening personnel as undergoing cyclic vibration while the field sheet entries for 9.9 percent of components was left blank. Except for Refinery C, components at each of the petroleum refineries was identified as undergoing cyclic vibration.

The number and percentage of screened components by cyclic vibration category and screening net measurement (maximum screening measurement minus background screening measurement) are shown in Table III-34 and Table III-35.

The table listed values are also shown in figures encompassing the entire screening value range (0 ppmv to > 10,000 ppmv) as well as figures split by screening range (0 ppm to 500 ppmv and 501 ppmv to > 10,000 ppmv) in Figure III.22, Figure III.23, Figure III.24, Figure III.25, Figure III.26, and Figure III.27.

The cumulative percentage of screened components by cyclic vibration category (yes, no, unknown) and screening net measurement range is provided in Figure III.28.

Table III-34. Distribution of Screened Components by Cyclic Vibration and Screening Net Measurement

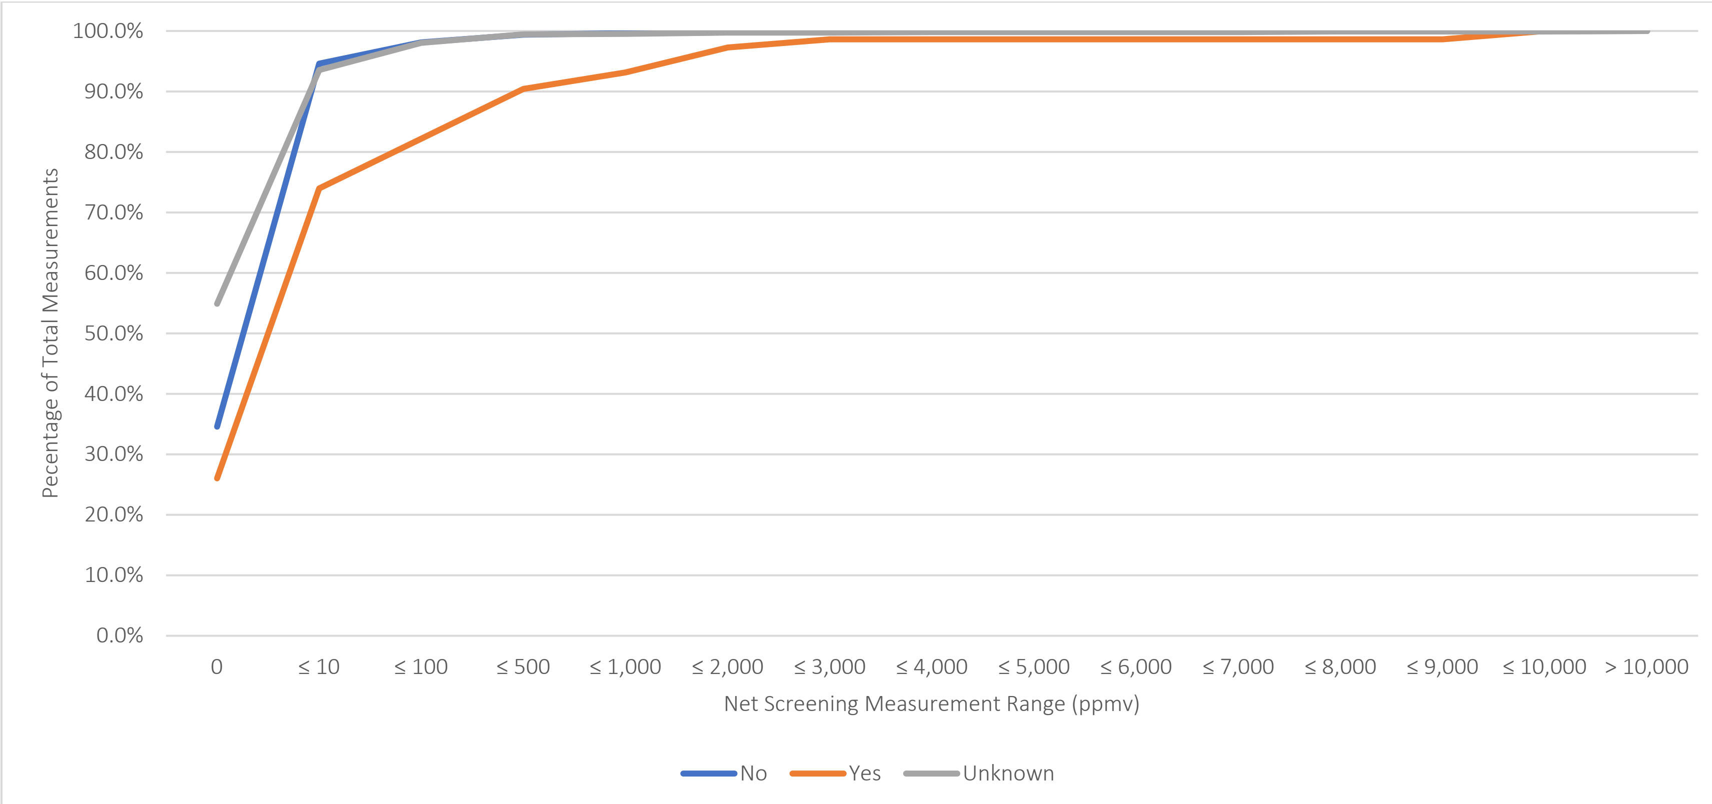

Figure III.28. Cumulative Percentage of Screened Components by Cyclic Vibration and Screening Net Measurement Range

Component Location

Most (72 percent) screened components were at the ground level while only five percent were located at the top of a column (presumably the furthest away from ground level).

The distribution of screened components by component location and screening net measurement range is listed in Table III-36 and shown in Figure III.29.

Three figures are provided for the percentage of screened components within each component location category by screening net measurement range:

- one providing the full scale of screening values (0 ppmv to > 10,000 ppmv, Figure III.30),
- one only showing percentage distribution for components with screening net measurements between 501 ppmv to > 10,000 ppmv (Figure III.31), and
- one only showing the percentage distribution for components with screening net measurements between 0 ppmv and 500 ppmv (Figure III.31).

Table III-36. Distribution of Screened Components by Location / Elevation and Screening Net Measurement

Component Monitoring Time and Pace

Monitoring time for screened components varied from equal to or less than one minute to 36 minutes. When accounting for component size, monitoring pace varied from less than one second per inch to over 500 seconds per inch.

Most (53 percent) components were screened in one minute or less and 87 percent were screened in under three minutes.

The number of and percentage of screened components by monitoring time are provided in Table III-38 and Table III-39.

The distribution of screened components by screening pace (seconds of screening time per component circumferential inch) is listed in Table III-40 and Table III-41.

Component A-477 is treated as a leak of greater than 10,000 ppmv because of both the magnitude of the leak at a distance and the presence of a continual hydrocarbon liquid leaks. However, because the component could not be screened at the required screening distance, the time to measure component A-477 may not be representative of similar leaks that could be screened at the surface.

The cumulative percentage of all screened components within a screening net measurement range (0 ppmv, 1 – 10 ppmv, 11 to 100 ppmv, 101 ppmv to 500 ppmv, etc.) by screening time is plotted and shown in Figure III.33 and Figure III.34. Two figures are provided to aid differentiating the separate curves.

Plots for the following screening ranges are not included in the two figures:

- 4,001 ppmv to 5,000 ppmv (only two components in this category, both screened for four minutes),
- 6,001 ppmv to 7,000 ppmv (zero components in this category),
- 8,001 ppmv to 9,000 ppmv (zero components in this category), and
- 9,001 ppmv to 10,000 ppmv (only one component in this category).

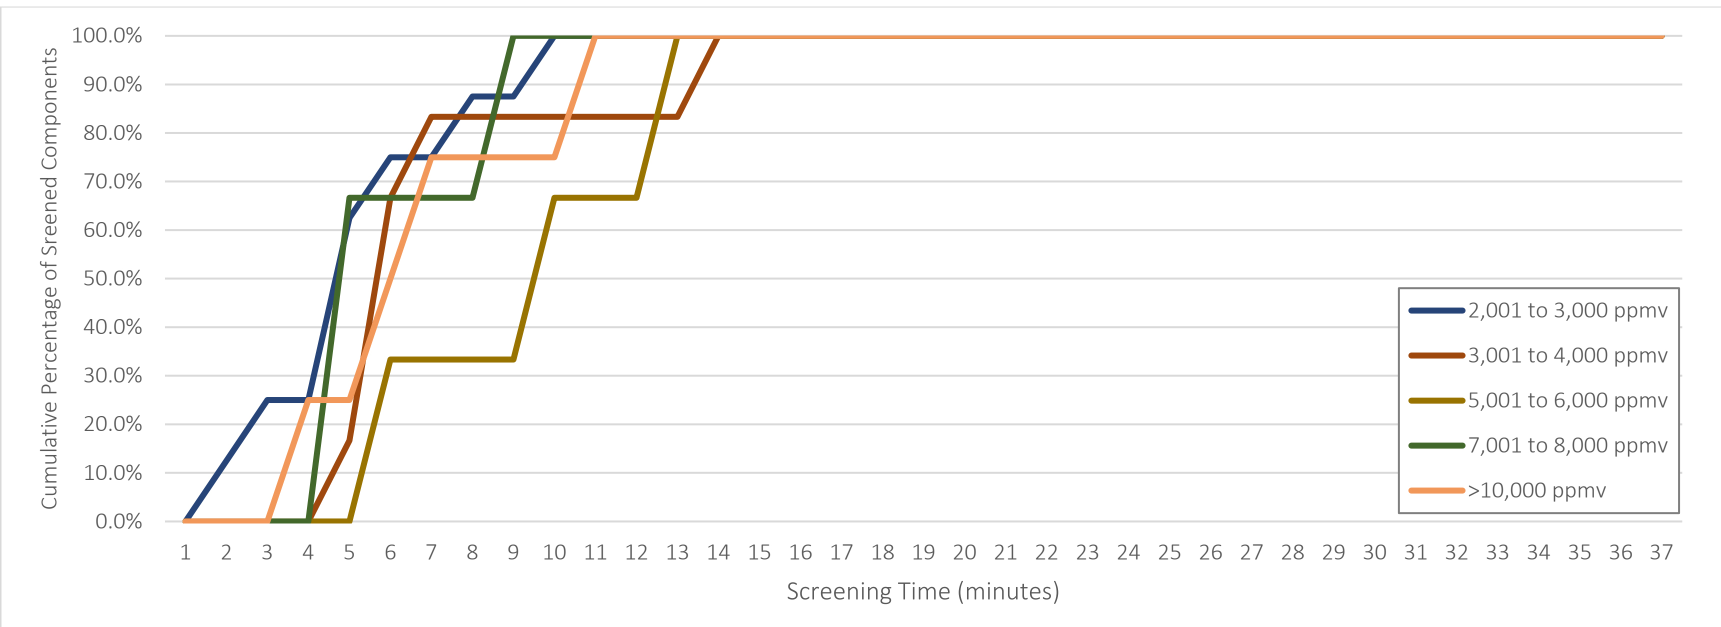

Figure III.34. Cumulative Percentage of Screened Components by Screening Net Measurement Range and Screening Time (2,000 ppmv to >10,000 ppmv)

iii. Mass Emissions Sampling

Mass emissions sampling ("bagging") began at Refinery A in January 2017 before screening at Refinery A had completed and prior to beginning screening at Refinery B. Per the methodology at the time, components with the highest 20 screening measurements were candidates for sampling by the third-party contractor (Tricord). The Air District sampled eight components at Refinery A: three duplicates of components (A-901, A-1050, and A-1730) sampled by the third-party contractor and six others. The Air District did not sample components at any other refinery apart from Refinery A.

Sampling occurred at the petroleum refineries over 99 days between January 2017 and November 2018.

Table III-42. Months and Years in Which Screening and Sampling Occurred

Petroleum Refinery	Study Months	
	Screening	Sampling
A	November 2016 through February 2017	January through March 2017
B	June 2017, July 2017, March 2018	July 2017, April 2018, May 2018
C	February 2018, March 2018, May 2018	May through July 2018
D	February and March 2018	March 2018, April 2018, November 2018
E	April and May 2018	August through November 2018

Components were sampled as soon as two days after screening and as long as 308 days after screening. The average number of days between screening and sampling was 100 days with a median of 80 days.

Except for five components at Refinery C, all sampled components were selected from components that were included in the field screening portion of the Study.

The five components at Refinery C that were identified outside of the field screening were:

- Sample C043: Tank Farm connector (plug) handling tar with a pre-bag leak of 41 ppmv,
- Sample C045: Tank Farm connector (tube fitting) handling tar with a pre-bag leak of 41 ppmv,
- Sample C047: Tank Farm agitator seal handling diesel with a pre-bag leak of 15 ppmv,
- Sample C049: Tank Farm connector (tubing) handling tar with a pre-bag leak of 230 ppmv, and
- Sample C054: Hydrocracker connector (threaded) handling hot oil with a pre-bag leak of 12 ppmv.

The components were identified by Refinery C personnel. It is not known how these components were identified by the refinery personnel.

III.iii.1. Field Observations

Sampling personnel identified numerous items that impacted sampling and/or may have had an impact on sampling results:

- High component temperatures melted physical tags that were affixed during field screening. In some cases, Mylar used for sampling was melted and a tin foil bag was used. In others, aluminum foil and/or high temperature tape was used to seal hot or irregular surfaces.

- Because of high component temperatures, some selected components could not be sampled. During sampling at Refinery B, the sampling team imposed an upper boundary (approximately 400 degrees Fahrenheit) on component external temperatures that could be sampled and stated that no components with temperatures above this this threshold could be sampled.
- Third-party sampling personnel created small holes in tent enclosures to “vent bag” to reduce off-scale vacuum. In these cases, either ambient air was pulled into the tent and through the sampling media or component leakage was emitted out of the tent. This impacted 39 samples (approximately 23 percent of the samples).
- Liquid samples (condensate) were collected from 11 samples where liquids formed in the bag and/or sample line. However, there were instances where liquid could not be collected. Component B-2040 had dripping product from a pump seal but because the pump was oriented vertically, a sample could not be collected. While sampling component A-1050, an oily sheen was formed in the bag but there was insufficient amount to collect or measure. The Mylar tent material itself was not shipped for laboratory analysis. For two samples collected by the Air District (component A-22 and component A-39), condensate was collected for both primary and replicate samples. However, because the components had pre-existing material on the surface of each component, it could not be determined whether the collected condensate was from the leak or liquefying of the surface material, so the collected condensate mass was not included with the sorbent tube results.
- Samples were sent for off-site laboratory analyses in overnight deliveries. However, samples were sent in batches with up to 15 days elapsing from sampling date and shipping date.
- Several sample media were found to have cracked or broken tube caps either in the field or when received by the laboratory:
    - Sample A017A1 XAD tube was received broken although the tube media was able to be recovered.
    - Samples D03A2 (D-596), D04A2, and D023A1 (component D-979) were received by the laboratory with cracked caps.
    - Sample D034 (component D-596) A1 charcoal tube broke at the top.
    - Sample B015 (component B-1314) charcoal tube A2 broke at the end.
    - After sampling of Sample B036 (component B-1099), the sampling team could not find caps for the tubes and temporarily wrapped tubing ends in Teflon tape.
- Field conditions during sampling varied. For example, while sampling of component C-20067-P, there was welding approximately 36 feet upwind of the pump. Sampling of component A-1742 was approximately 8 feet way from work being performed on an open sewer line and excavated pavement. Component D-1149 could not be sampled because of inaccessibility due to scaffolding erected between the time of field screening and sampling.
- Some components had material at or near the leak interface that interfered with sampling:
    - Component 1083 had accumulated solidified material that prevented a proper seal for tenting. Sampling personnel used a wire brush to scrape scaling on the sides of flanges for better adhesion of sealing materials.

- Sample D050 (component D-1367) had heavy buildup that was cleaned.

- Operations varied during field screening and sampling. In some cases, sampling personnel requested process unit operators to operate differently for the purposes of sampling. For example, for sample C018 (component C-20402.2), sampling personnel asked operators to turn on a closed loop.

- Tricord sampling pump flow rate limitations increased required sampling times. After Refinery A, Tricord sampling personnel requested to remove the XAD tubes to increase sampling times. This reduced the number of sampling tubes from three (one XAD tube, two charcoal tubes) to two (two charcoal tubes). The reduction in sampling tubes may have increased the likelihood of breakthrough. Breakthrough of the second tube of sample C004 (component C-20048) was indicated by the laboratory as likely occurring.

The following observations were also made:

- Leaking concentration measurements taken prior to sampling ("pre-bag" measurements) often varied significantly from those measured during field screening. The most significant difference was for sample C004 (component C-20048) where field screening measured a leak concentration of 5,482 ppmv and pre-bag screening measured 28,300 ppmv.
- Components not in operation still had emissions. For example, component C-20706 (sample C016) was a pump that was off, and sampling personnel were told by an operator that the pump had not be in operation for 15 years. Field screening measured a leak from this pump of 30 ppmv while pre-bag measured at background (net measurement equaled zero ppmv).

III.iii.2. Measurements

A total of 165 unique components at the five petroleum refineries were sampled. Samples at Refinery A were collected using a XAD tube in series with two coconut charcoal tubes while samples at the other refineries were collected using only two coconut charcoal tubes.

The distribution of samples and summary of average sample results by refinery is presented in Table III-43 and a histogram provided in Figure III.35.

Table III-43. Summary of Mass Emissions Sampling by Petroleum Refinery for Sorbent Tube Results

			Average Sample Emissions (2)	
Petroleum Refinery	Number of Samples (1)	Percentage of Total Samples (%)	Minimum (kg/hour)	Maximum (kg/hour)
A	25	15	1.72E-05	3.66E-03
B	30	18	1.17E-06	1.62E-03
C	28	17	1.19E-06	1.38E-02
D	40	24	1.16E-06	2.30E-02
E	42	26	1.13E-06	4.01E-03
Total	**165**	**100**	**1.13E-06**	**2.30E-02**

Notes:
1. Only includes number of unique component samples and does not include number of samples taken for quality control purposes (duplicate, background, spike, and trip).
2. Average of primary and replicate sample results

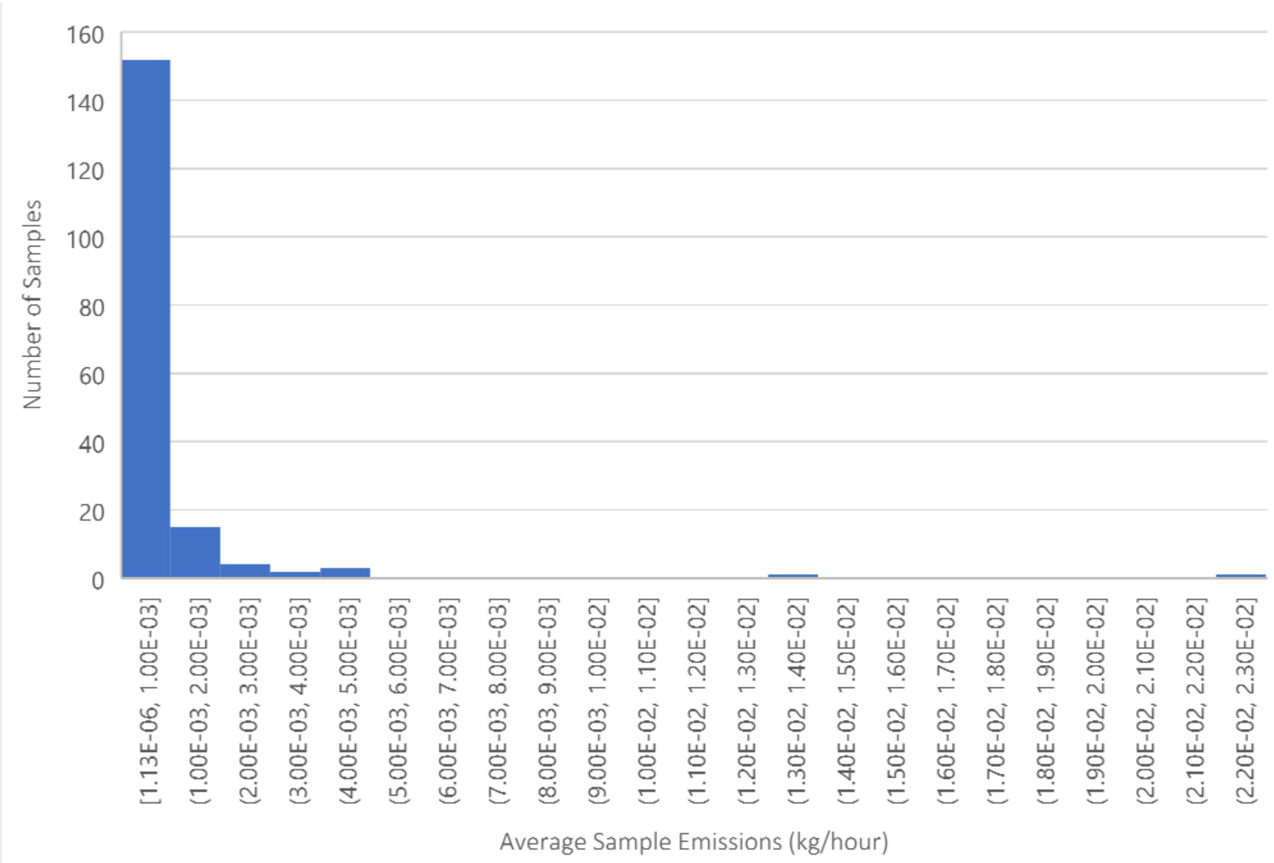

Figure III.35. *Histogram of Mass Emissions Sampling Results for Sorbent Tubes*

III.iii.2.1. Sampling for Lighter Compounds

Since the sorbent tubes were only analyzed for C_5 to C_{24} compounds and were not suited for lower carbon compounds, evacuated canister samples were collected in addition to sorbent tube samples for four components at Refinery A: components, A-22, A-39, A-902, and A-1083. Canister samples were not collected at any other refinery.

For these samples, EPA Method 18 was used to identify and quantify methane while EPA Method TO-14A was used to identify the presence and quantities of the following C_2 to C_6 compounds:

- Ethylene (C_2H_4)
- Acetylene (C_2H_2)
- Ethane (C_2H_6)
- Propylene (C_3H_6)
- Propane (C_3H_8)
- Isobutane (C_4H_{10})
- 1-Butene (C_4H_8)
- Butane (C_4H_{10})
- trans-2-Butene (C_4H_8)
- cis-2-Butene (C_4H_8)
- Isopentane (C_5H_{12})
- 1-Pentene (C_5H_{10})
- Pentane (C_5H_{12})
- Isoprene (C_5H_8)
- trans-2-Pentene (C_5H_{10})
- cis-2-Pentene (C_5H_{10})
- 2,2-Dimethylbutane
- Cyclopentane (C_5H_{10})
- 2,3-Dimethylbutane (C_6H_{14})
- 2-Methylpentane (C_6H_{14})
- 3-Methylpentane (C_6H_{14})
- 1-Hexene (C_6H_{12})
- Hexane (C_6H_{14})
- Methylcyclopentane (C_6H_{12})
- Benzene (C_6H_6)
- Cyclohexane (C_6H_{12})

In addition, EPA Method TO-15 was used to identify and quantify the following compounds:

- Propylene
- Freon 12
- Freon 14
- Chloromethane
- Chloroethene (Vinyl chloride)
- 1,3-Butadiene
- Bromomethane
- Chloroethane
- Bromoethene (Vinyl bromide)
- Freon 11
- Ethanol
- Acrolein
- Freon 113
- 1,1-Dichloroethene
- Acetone
- Carbon disulfide
- Isopropyl Alcohol
- Allyl chloride (3-chloropropene)
- Acetonitrile
- Hexane
- 1,1-Dichloroethane
- Vinyl acetate
- cis-1,2-Dichloroethylene
- Methyl ethyl ketone (2-Butanone)
- Ethyl acetate
- Chloroform
- Tetrahydrofuran
- 1,1,1-Trichloroethane
- Cyclohexane
- Carbon tetrachloride
- Benzene
- 2,2,4-trimethylpentane
- 1,2-Dichloroethane
- Heptane
- Trichloroethene
- 1,2-Dichloropropane
- Methyl methacrylate
- 1,4-Dioxane
- Bromodichloromethane
- cis-1,3-Dichloropropene
- Methyl isobutyl ketone
- Toluene
- trans-1,3-Dichlorpropene
- 1,1,2-Trichloroethane
- Tetrachloroethene
- 2-Hexanone (Methyl butyl ketone)

The four components were in two different process units: a fluidized catalytic cracking unit (A-022, A-039) and a hydrotreater (A-0901, A-1083).

They handled different stream materials: recycled gas oil (A-022), light gas oil / heavy gas oil (A-039), diesel (A-0901), and fractionator bottoms (A-1083).

Each had different pre-bag screening measurements: 1,600.0 ppmv (A-022), 332.8 ppmv (A-039), 493.3 ppmv (A-0901), and 17.6 ppmv (A-1083).

Sample results for the four components by collection device (canister or sorbent tube) and test method (TO-14A, TO-15, EPA Method 18) are presented in Table III-44.

Table III-44. Total Emission Rates Measured by Sample Collection Method and Method

Sample	Total Emission Rates (kg/hour)			
	Canister TO-14A / Method 18 (1) C_1 to C_6 Compounds	Canister TO-15 C_1 to C_{10} Compounds	Primary Sorbent Tube Method 18 C_5 to C_{30} Compounds	Replicate Sorbent Tube Method 18 C_5 to C_{30} Compounds
A-022	4.30E-07	3.22E-06	2.68E-04	1.39E-04
A-039	2.50E-08	3.33E-06	1.85E-04	2.54E-04
A-901	1.23E-07	2.01E-07	1.40E-04	1.21E-04
A-1083	7.60E-08	1.53E-07	4.63E-05	8.57E-06

Note:
1. EPA Method 18 used for detecting and measuring methane

Sample results by collection method and by grouping pollutants by carbon number are plotted for sample concentrations (Figure III.36, Figure III.38, Figure III.40, Figure III.42) and by emission rate (Figure III.37, Figure III.39, Figure III.41, Figure III.43).

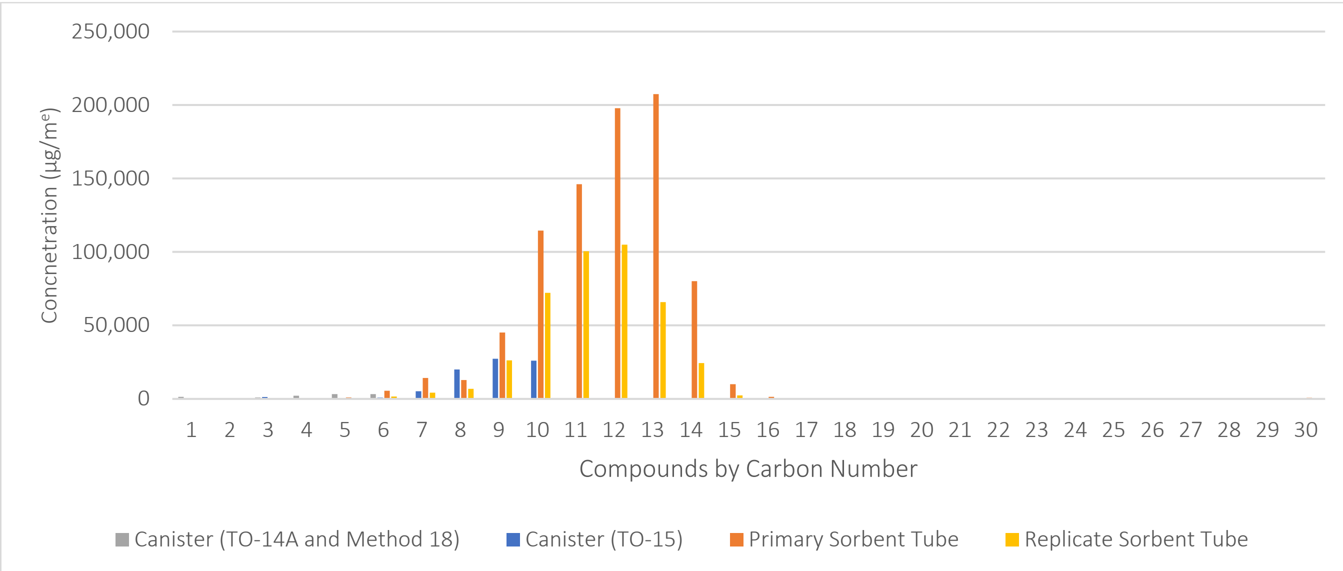

Figure III.36. Canister and Sorbent Tube Concentration Results for Sample A-22

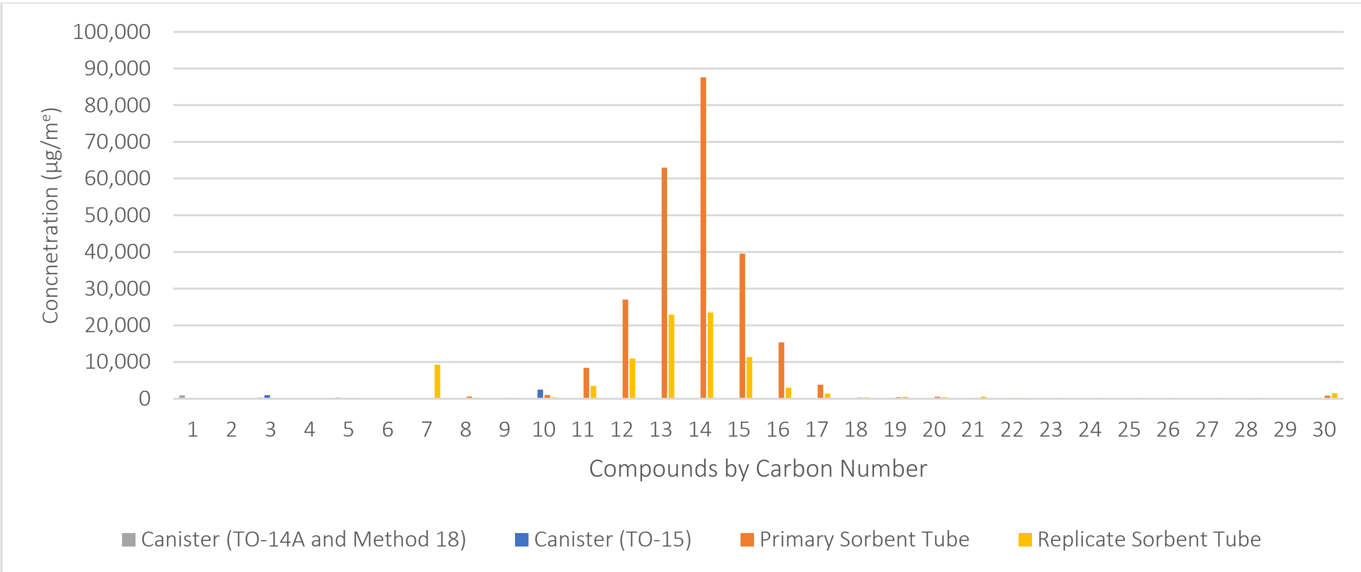

Figure III.42. Canister and Sorbent Tube Concentration Results for Sample A-1083

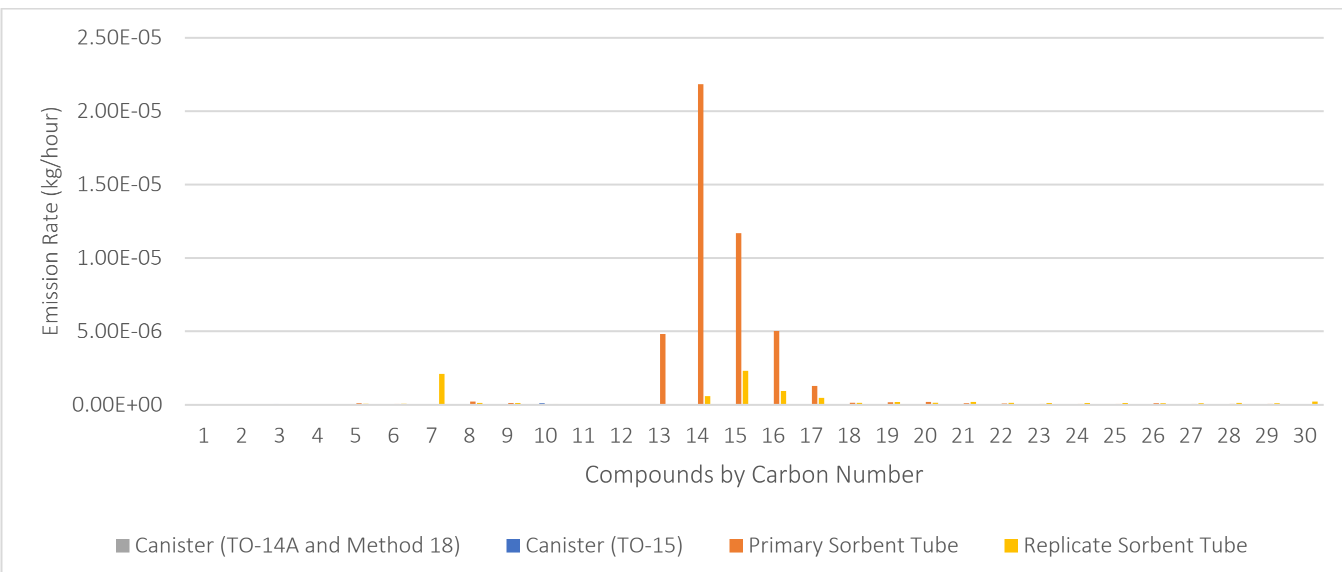

Figure III.43. Canister and Sorbent Tube Emission Results for Sample A-1083

Canister sample results from the four components are not included in any of the subsequent sections on sample results.

III.iii.2.2. Process Units

Not all process units that had components screened had components sampled. Some general process units / areas are not represented. Of the components that were screened by general process unit / area, the number of components sampled varied. Hydrotreating process units were sampled the most by total number while blending and tank farms were sampled the most by percentage of components screened (see Table III-45).

Table III-45. Number of Components Sampled by General Process Unit / Area Category

General Process Unit / Area Category	Number of Components Screened	Number of Components Sampled	Sampled (%)
Aromatic Saturation	8	1	13
Asphalt Plant	71	2	3
Blending / Tank Farm	8	2	25
Catalytic Cracking	875	10	1
Catalytic Reformer	2	0	0
Coker	1,450	5	0.3
Crude Unit	1,123	8	1
Crude Unit / Coker	159	2	1
Fuel Gas Treatment	53	0	0
Gas Recovery	22	0	0
Hydrocracker	1,074	38	4
Hydrogen Production	32	0	0
Hydrotreater	4,464	72	2
Hydrotreater and Hydrocracker	834	0	0
Isomerization	1	0	0
Marine Terminal	10	0	0
Other	25	2	8
Polymerization	11	0	0
Reformulation	17	1	6
Separation	9	0	0
Solvent Deasphalting	26	0	0
Sulfur Recovery	114	1	1
Tank Farm	433	21	5
Utilities	2	0	0
Total	10,823	165	1.5

The distribution of total mass emissions from all samples by general process unit / area also varied as shown in Table III-46 and Figure III.46.

Table III-46. Distribution of Total Hydrocarbon Emissions from Sampled Sources by Process Unit / Area Category

General Process Unit / Area Category	Sampled	Sampled (%)	Total Emissions (kg/hour)	% of Total Source of Measured Emissions
Aromatic Saturation	1	0.6	1.89E-06	0.002

Total	**165**	**100**	**9.99E-02**	**100**

Notes:

1. Does not include results of duplicate samples. For components that had repeated samples, only the first sample results are included.

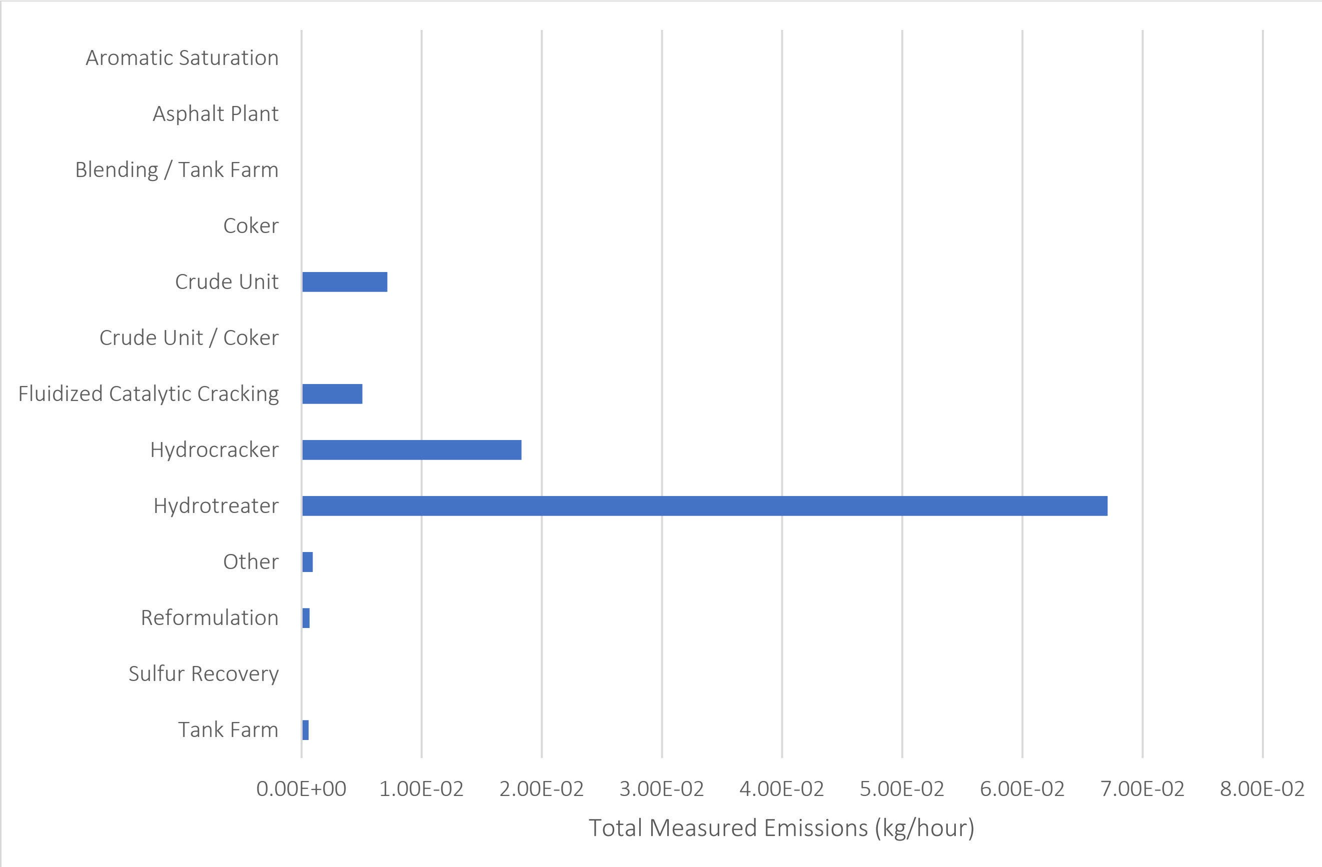

Figure III.44. Total Measured Emissions from All Samples by General Process Unit / Area

As shown in Table III-46 and Figure III.44, components within hydrotreaters comprised most of the sampled components (43.6 percent) and of sampled emissions (67.1 percent).

III.iii.2.3. Component Types and Subtypes

Of the total samples, pump seals, connectors, and valves represented approximately 19 percent, 37 percent, and 44 percent, respectively. The distribution of samples and total measured emissions by component type are provided in **Table III-47** and **Table III-48**.

Table III-47*. Number of Samples by Component Type*

Component Type	Number Screened	Number Sampled	Sampled (%)
Pump Seals	734	32 [(1)]	4
Connectors	4,710	61	1
Valves	5,349	72	1
Pressure Relief Devices	30	0	0
Total	**10,823**	**165**	**1.5**

Note:
1. Includes one sample of a storage tank agitator seal leak.

Total		**10,823**	**165**	**1.5**

Notes:
1. Does not include results of duplicate samples. For components that had repeated samples, only the first sample results are included.
2. Includes one sample of a storage tank agitator seal leak.
3. Two pressure safety valves were sampled. Both pressure safety valves did not have an opening to atmosphere and sample enclosure included connection at flange. These samples were classified as connectors.

Measured sample emissions by component subtype are listed in Table III-50.

Because pressure relief valves were not sampled and the subtypes for pumps was unknown, only connectors and valves are listed in the table.

Component Operating Pressure

The operating pressure of sampled components varied from less than 5 psig to 2,200 psig. However, the operating pressure of approximately 28 percent of the samples is unknown (Figure III.50 and Table III-54). Total emissions from components with unknown operating pressure represented 17 percent of the total measured emissions from all samples (Table III-55 and Figure III.51).

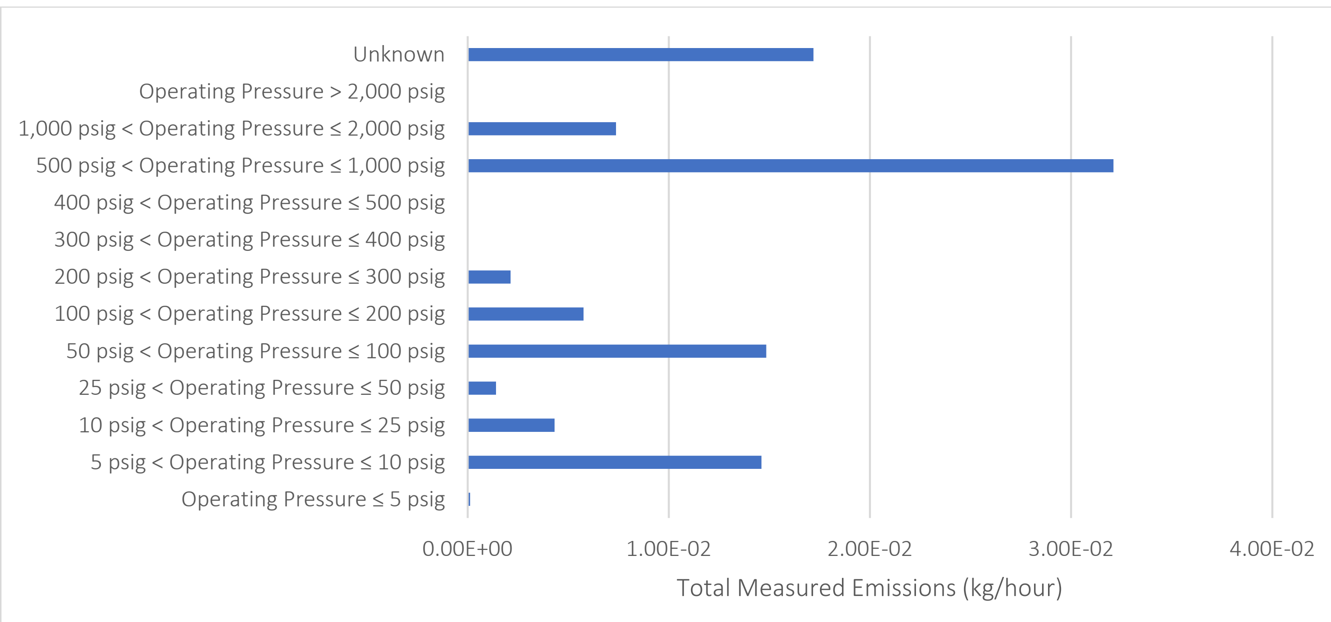

Figure III.51. Measured Total Hydrocarbon Emissions from All Samples by Component Operating Pressure

Primary sample results (on a logarithm scale) by component operating pressure and component type are shown in Figure III.52. Results from duplicate sampling of the same component are not provided.

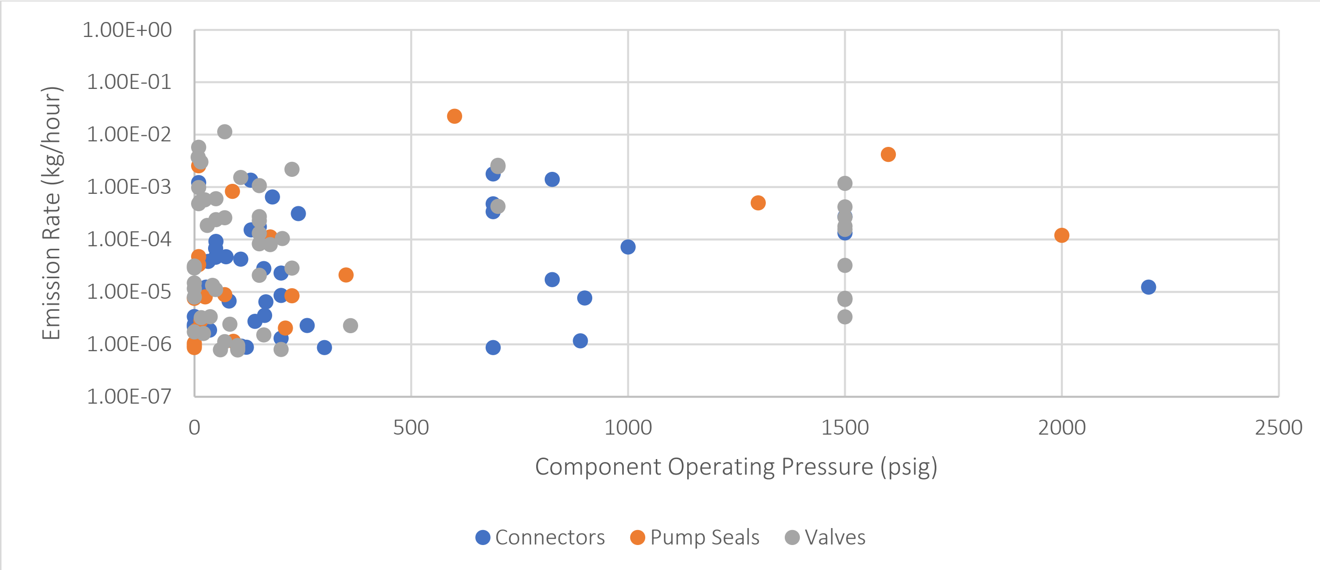

Figure III.52. Primary Sample Results (logarithm scale) by Component Operating Pressure and Component Type

Component External Temperature

Sampled components had external temperatures ranging from 48 degrees Fahrenheit to 540 degrees Fahrenheit. Most sampled components had external temperatures less than 100 degrees Fahrenheit. The external temperature of only one component (A-039) during sampling is unknown. A temperature was not recorded during either screening or sampling of the component.

The distribution of component samples and total measured emissions by external temperature categories (intervals of 100 degrees Fahrenheit) is provided in the following tables and figures.

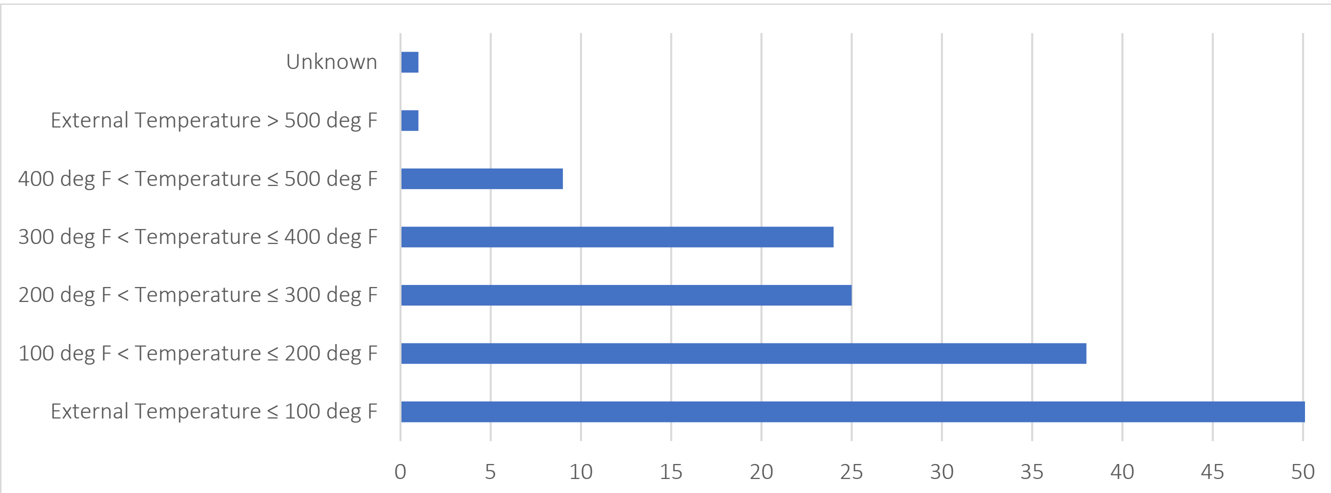

Figure III.53. *Count of Mass Emission Samples by Component External Temperature*

Table III-56. *Number of Samples by Component External Temperature*

External Temperature (Degrees Fahrenheit)	Number Screened	Number Sampled (1)	Sampled (%)
External Temperature ≤ 100 deg F	4,476	67	41.4

Measured emissions of primary samples by component type and component external temperature are shown in Figure III.55.

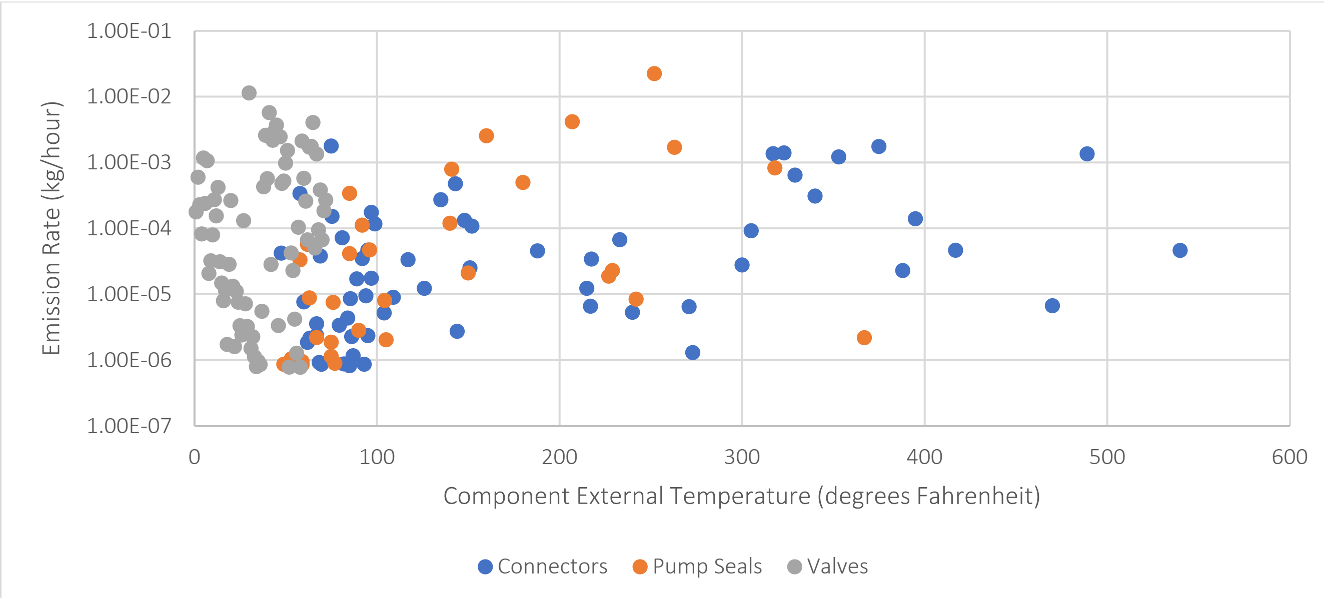

***Figure III.55**. Primary Sample Results (logarithm scale) by Component External Temperature and Component Type*

Component Vibration

Approximately 93 percent of sampled components were identified by screening field personnel as having low to no vibration (see Table III-55). Five components classified as having high vibration were sampled while the vibration amount of five other sampled components was unknown.

Table III-58. Distribution of Total Hydrocarbon Emissions from Sampled Sources by Component Vibration

Vibration Amount	Sampled	Sampled (%)	Total Emissions (kg/hour)	% of Total Emissions
None	74	44.8	3.61E-02	36.1
Low	80	48.5	6.31E-02	63.2
Medium	1	0.6	4.32E-06	0.004
High	5	3.0	6.06E-04	0.6
Unknown	5	3.0	5.76E-05	0.1
Total	**165**	**100**	**9.99E-02**	**100**

Total measured emissions from all samples by identified vibration amount is presented in Figure III.56.

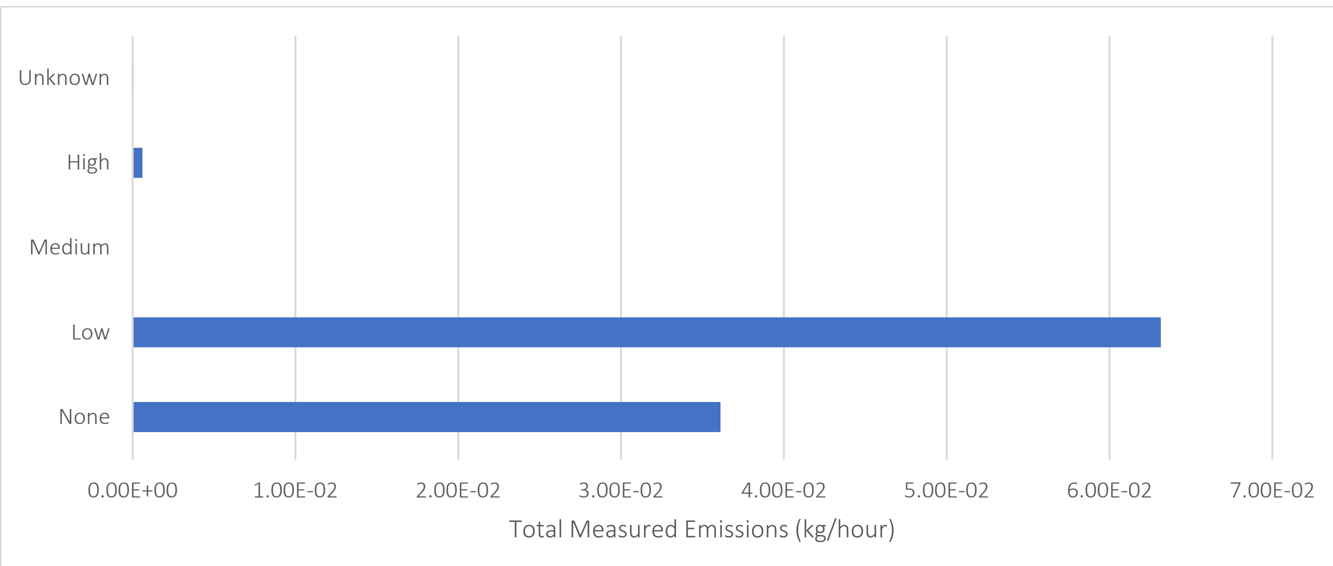

Figure III.56. Measured Total Hydrocarbon Emissions from All Samples by Component Vibration

Cyclic Vibration

Only eight components (representing 4.8 percent of all samples) categorized as undergoing cyclic vibration by screening field personnel were sampled. Most (80.6 percent) sampled components were identified as not undergoing cyclic vibration.

Summary counts and total emissions by cyclic vibration categorization are shown in Table III-59 and Figure III.57.

Table III-59. Distribution of Total Hydrocarbon Emissions from Sampled Sources by Cyclic Vibration

Cyclic Vibration	Sampled	Sampled (%)	Total Emissions (kg/hour)	% of Total Emissions
None	133	80.6	8.73E-02	87.4
Yes	8	4.8	7.71E-03	7.7
Unknown	24	14.5	4.88E-03	4.9
Total	**165**	**100**	**9.99E-02**	**100**

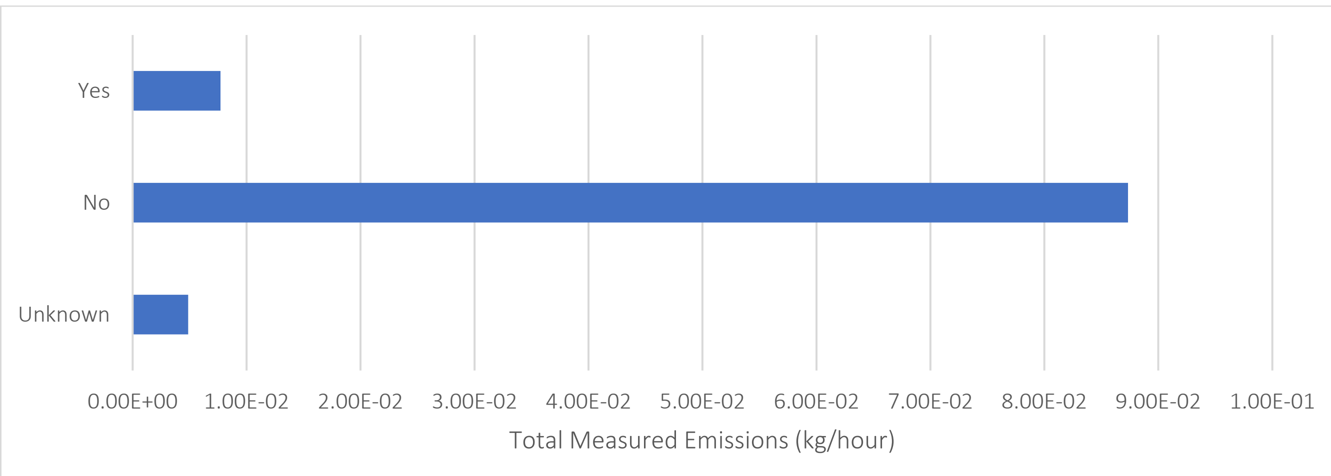

Figure III.57. Measured Total Hydrocarbon Emissions from All Samples by Cyclic Vibration

Component Location / Elevation

The general component location (ground, platform, top of column, or other) for five sampled components was not known. These were the five components (Samples C043, C045, C047, C049, and C054) that were not included in the field screening portion of the Study but were identified by Refinery C personnel for sampling. Four of the five were in a tank farm so were likely at ground level. The fifth component was in a hydrocracker and could have been in any of the four general locations.

The number of sampled components as well as the total measured mass emissions by general location category are provided in Table III-60 and **Figure III.58**.

Table III-60. Distribution of Total Hydrocarbon Emissions from Sampled Components by Component Location (Elevation)

Component Location	Sampled	Sampled (%)	Total Emissions (kg/hour)	% of Total Emissions
Ground	131	79.4	7.72E-01	71.9
Platform	23	13.9	2.01E-01	21.4
Top of Column	4	2.4	2.54E-02	5.5
Other	2	1.2	6.79E-04	0.7
Unknown	5	3.0	5.77E-04	0.5
Total	**165**	**100**	**9.99E-02**	**100**

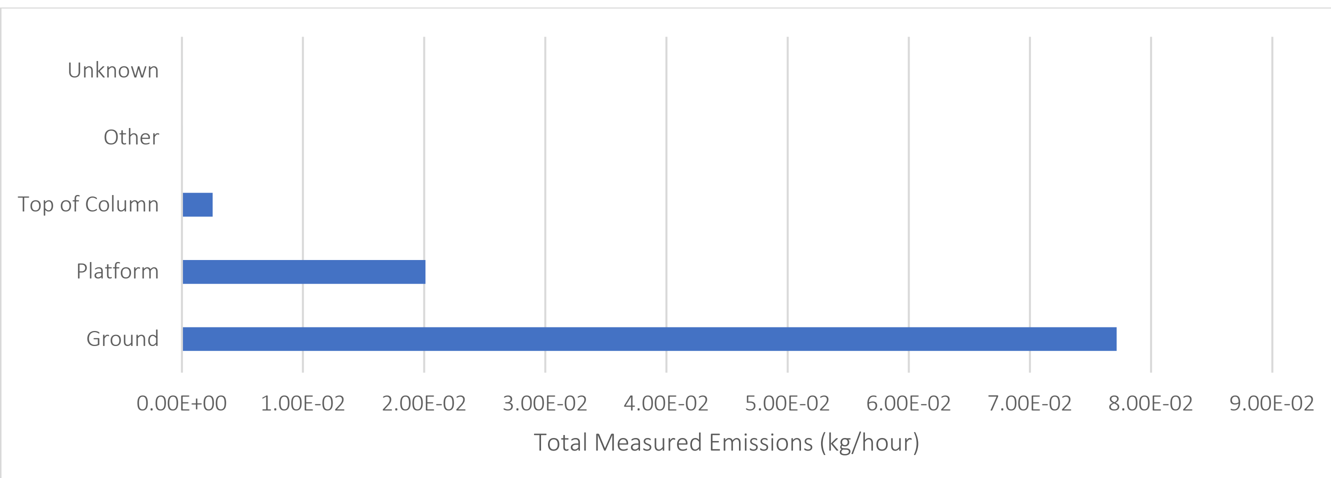

***Figure III.58**. Measured Total Hydrocarbon Emissions from All Samples by Component Location (Elevation)*

Screening Value

Measured emissions varied directionally by screening value as shown in Figure III.59 where results of primary samples by screening net measurement (where background concentration measurement is subtracted from a component's pre-bag maximum screening value) and component type is presented.

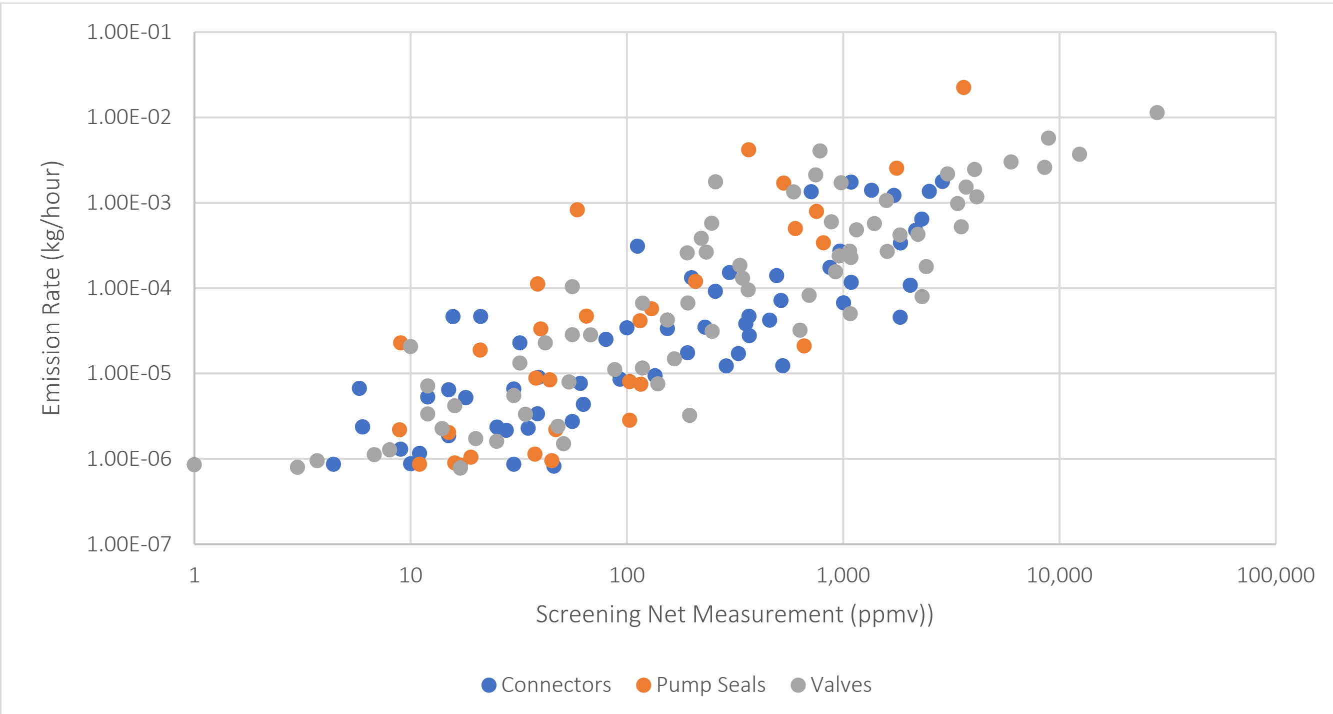

Figure III.59. *Primary Sample Results (logarithm scale) by Screening Net Measurement (logarithm scale) and Component Type*

iv. Emission Estimates of Both Sampled and Non-Sampled Components

Over 10,000 components were screened for equipment leaks while only 165 components had mass emissions measured. Therefore, it was necessary to derive a method for estimating emissions from non-sampled components.

In addition, because sampling of selected components occurred later than field screening (with as many as 308 days elapsing between screening and sampling), components that were sampled may have had different emissions at the time of sampling than at the time of screening due to process, operational, or other changes.

Most of the field screening data that was collected included the petroleum refinery, process unit, process unit sub-area, component type, component subtype, stream material, component size, external temperatures of the components, component operating pressure, component elevation in addition to leak concentration measurements.

III.iv.1. Regression Analysis

From the sampled (bagged) data, a relationship between two or more covariates may be modeled using regression analysis to estimate mass emissions from components that were screened but not sampled.

Information collected during field screening and sampling was analyzed to develop an equation for estimating emissions from screening data. A detailed description of the statistical analysis is provided in Appendix D-1.

From this analysis, linear equations were developed for predicting mass emissions. As with previous studies, log transforms of the measured emission rate and screening value were found to better fit the linear regression model. Since some net screening values were zero, it was not possible to take the logarithm of every value. Two approaches were used to account for this: 1) add a constant to every screening value (10 was used), or 2) limit the use of the regression equations to those components that had screening values above a threshold (10 ppmv was chosen). The equations for both approaches had the following form:

$$\hat{y}_i = a + b*\log_{10}[\text{Screening Value}_i] + c*[\text{Component Temperature}_i] \qquad \text{[III-2]}$$

where:

$\hat{y}_i$	= predicted log (emission rate (kg/hour))
i	= component
a, b, c	= regression parameters, a = intercept, b and c = coefficients
Screening Value	= maximum screening measurement (ppmv), for Approach 1) a constant of 10 was added
Component Temperature	= component external temperature

Separate regression equations were developed for pumps and valves and connectors with regression parameters shown in the following table.

Table III-61. Regression Parameters

Component Type (Model)	Regression Parameters			Regression Standard Errors			Adjusted R^2	Sigma	n
	Intercept (a)	Screening Value (b)	Temperature (c)	Intercept	Screening Value	Temperature			
Pumps (1)	-7.98	1.41	0.0044	0.19	0.19	0.0014	71.3	0.65	30
Pumps (2)	-7.70	1.21	0.0062	0.39	0.20	0.0018	75.0	0.62	27
Valves and Connectors (1)	-7.45	1.12	0.0026	0.12	0.05	0.0003	84.6	0.41	131
Valves and Connectors (2)	-7.27	1.05	0.0027	0.14	0.05	0.0003	82.4	0.42	188

However, the regression equations do not exactly predict measured emissions of sampled components as shown in Table III-62, which compares the results of the total predicted emissions of those samples used to develop the equations with the total measured emissions of those samples.

Table III-62. Comparison of Regression Predicted Emissions with Measured Sampled Emissions

Component Type (Model)	Measured (kg/hour)	Predicted (Without Bias Adjustment)		Predicted (Bias Adjusted)	
		Predicted (kg/hour)	Predicted / Measured (%)	Adjusted (kg/hour)	Adjusted / Measured (%)
Pumps (1)	0.034	0.020	58	0.032	92
Pumps (2)	0.034	0.021	62	0.033	95
Valves and Connectors (1)	0.049	0.036	73	0.054	109
Valves and Connectors (2)	0.049	0.036	72	0.054	110

As shown in the Table III-62, the regression equations predicted emissions that were an underestimate of what was measured. This difference between the predicted emissions and what was measured is attributed to measurement error and transformation scale bias as discussed in Appendix D-1.

III.iv.2. Simulation

Predicted emissions for a component were derived using regression equations in the logarithm scale. However, the mean leak rate was determined on the original scale.

When regression is accomplished on one scale by transforming data and then the resulting regression-derived values are de-transformed, an additional error is introduced termed transformation scale bias. The 1980 EPA Study corrected for this bias through use of a Scale Bias Correction Factor. However, this approach was found (see Appendix D-1) to be not appropriate for this Study. Rather, to adjust for this, simulation of regression errors was performed (discussed in detail in Appendix D-1). As shown in Table III-62, the ratios of the adjust predictions to measured values were near (within 10 percent) of 100 percent, falling within statistical uncertainty of 100 percent. Thus, the model adjustments appeared adequate.

III.iv.3. Bootstrapping

Most pumps in heavy liquid service at each petroleum refinery were screened. However, only approximately six percent of the total estimated number of valves and less than two percent of the total estimated number of connectors were screened and included within the Study. To address sampling error for connectors and valves, bootstrapping with replacement was performed.

After estimating predicted emissions from screened connectors and valves using the regression equations forming an array of predicted emissions, a new data set of the same size as the original data set was created. Then for each place within the new data set, an observation from the original data set was randomly selected and placed within the new data set. From the newly created data set, the mean was determined. This process is repeated multiple times to create a set of means. These were used to estimate the mean leakage rates and to provide confidence intervals.

III.iv.4. Average Emissions Data Sets

During screening, several categories of components were identified as warranting a separate treatment for analysis. These include:

- components in heavy liquid service but within an LDAR program,
- components handling non-process lube oil,
- components handling gaseous phase heavy liquid streams, and
- pumps with steam injection pump seals.

In addition, any components that did not have any of the required information (screening value or temperature) to use the corresponding regression equation was excluded from analysis.

LDAR Components

There were 94 screened components at Refinery A and three screened components at Refinery B that were determined to be in heavy liquid service but were being routinely monitored within the refinery's LDAR program. As the intent of an LDAR program is to routinely monitor components for leaks and repair any leaks found, components within an LDAR program would be expected to have less leaks (both in magnitude and frequency) and corresponding less emissions than similar components not within an LDAR program. Therefore, including such components may bias emission estimates low.

Non-Process Lube Oil Components

Historically, components handling non-process lube oil, such as seal pots containing lubricating oil for pump seals, have not be included in emissions inventories as there is no established method for estimating the number of such components and emissions from such material at ambient conditions would not be expected to be great. As emissions from non-process lubricating oils were expected to differ from process lubricating oils at higher temperatures and pressure, it was decided to pull these components out of the Study and incorporate them into a separate study, the Lube Oil Study.

Storage Tank Area Components

Because components in heavy liquid service were not historically inventoried, the number of such components was estimated based on the known number of components in gas or light liquid service within certain process unit categories. However, this method does not account for process units for which there are heavy liquid service components but no gas or light liquid service components or for process units and / or areas that were not included within the EPA study from which the multipliers were derived. This includes storage tanks and tank farms. Therefore, current emissions inventories do not account for fugitive emissions from such areas including tank farms (emissions from storage tanks themselves are included in inventories). Such components include valves, connectors, and pump seals from piping leading to and away from storage tanks.

While screening at Refinery B, the petroleum refineries expressed a concern that by only including process unit components within the Study, average emissions may differ (expected to be higher) than components handling process streams at ambient temperatures and pressure such as those in the storage tank farms. Even though there was not a method for estimating the number of such components, there was a concern that emissions from such components would be overestimated if using average emission factors derived solely from process unit components. It was decided to include such components within the Study. However, because such components were included in the Study, a method for estimating and including such components into emissions inventories is needed.

Gaseous Phase Heavy Liquid Service

The five petroleum refineries have agreed to incorporate any components handling a heavy liquid stream in the gaseous phase within their LDAR programs. As such, it will be necessary to exclude these components from average emission factors meant to be used in the future for non-monitored components in heavy liquid service.

Steam-Injected Pump Seals

While screening at Refinery A, a pump seal leak of 760 ppmv was measured at a foot or more away from the seal with liquid hydrocarbons spewing from the seal. However, a screening at a closer distance (at the seal interface) was not possible as the pump had steam injection with steam billowing from the seal. Whenever, a screening instrument probe was placed too close to the interface, steam would condense within the screening instrument and cause it to malfunction. As previous studies have shown screening values to decrease with distance from the leak interface and the presence and rate of liquid hydrocarbon leaks, this pump was viewed as having a leak of over 10,000 ppmv and possibly with the highest emission rate of all components screened. However, because of the steam injection, this pump could not be sampled.

Several other similar pumps were found while screening. The presence of steam injection was identified as an important categorical delineation. In addition to the difficulty in screening at the proper distance and in sampling, steam injection at the seal introduces an additional leak forming mechanism that is not present in non-steam injected pumps that supports treating this sub-category of pumps differently.

III.iv.5. Analysis Results

The developed regression equations, bootstrap sampling technique, and simulation methods discussed above were used in computer programs created to estimate emissions from the screened components. The results of those estimates are presented in this section.

III.iv.5.1. Process Units

Total emissions by general process unit /area category are shown in Table III-63 and Figure III.60.

Table III-63. Distribution of Total Hydrocarbon Emissions by Process Unit / Area Category

III.iv.5.5. Sampling a Subset of Process Units

Prior to initiating the Study, the Air District and the five petroleum refineries agreed to only include two process units within the Study as a practical consideration. During the Study, the number of process units included expanded as necessary to meet the targeted number of screened components.

However, there were still a considerable number of process units / areas where connectors (non-pump housing or pump-associated) and valves were not screened and not included within the Study.

The following table includes a comparison of the total number of process units / areas where connectors (non-pump associated) and valves were screened compared to the total number of process units / areas at each petroleum refinery.

Table III-72. Comparison of the Number of Process Units / Areas Where Connectors and Valves Were Screened

Refinery	Number of Process Units / Areas in Study (1)	Total Number of Process Units / Areas (2)	Percentage of Total Units / Areas in Study (%)
A	4	42	10
B	7	27	26
C	5	75	7
D	4	64	6
E	5	36	14
Total	25	244	10

Notes:

1. Only includes units / areas where non-pump associated connectors and valves were screened
2. Based on the number of unique areas listed in each petroleum refinery's leak detection and repair program. May not include units / areas for which there are no components within the leak detection and repair program.

As shown in Table III-72, approximately 10 percent of the total process units / areas had non-pump associated connectors and valves screened within the Study.

As discussed in previous sections, process units / areas were selected and included within the Study to account for the diversity of process unit categories (crude unit, catalytic cracking unit, hydrotreater, etc.), process steams, and operating conditions (ambient temperature and pressure, operating temperature, operating pressure, etc.).

However, only a fraction of the total number of process units / areas had connectors and valves screened within in the Study, so the sampling was not at random, and there is an increase in the uncertainty of the overall results.

III.iv.5.6. Large Leakers

As shown from previous studies (see Table I-5 and Section I.iii.2 1970s Studies), emissions from components in heavy liquid service is dominated by a few large leakers. Over 80 percent of emissions is from approximately two percent of components. Most pump seals were sampled, but only about 10 percent of the estimated number of valves and five percent of the estimated number of connectors were sampled so, it is very likely that the largest valve and connector leakers were not sampled.

Using the regression estimates and cumulative probability theory (see Appendix D-1 for a detailed analysis), a cumulative distribution of the maximum emissions by component type was derived and shown in Figure III.66.

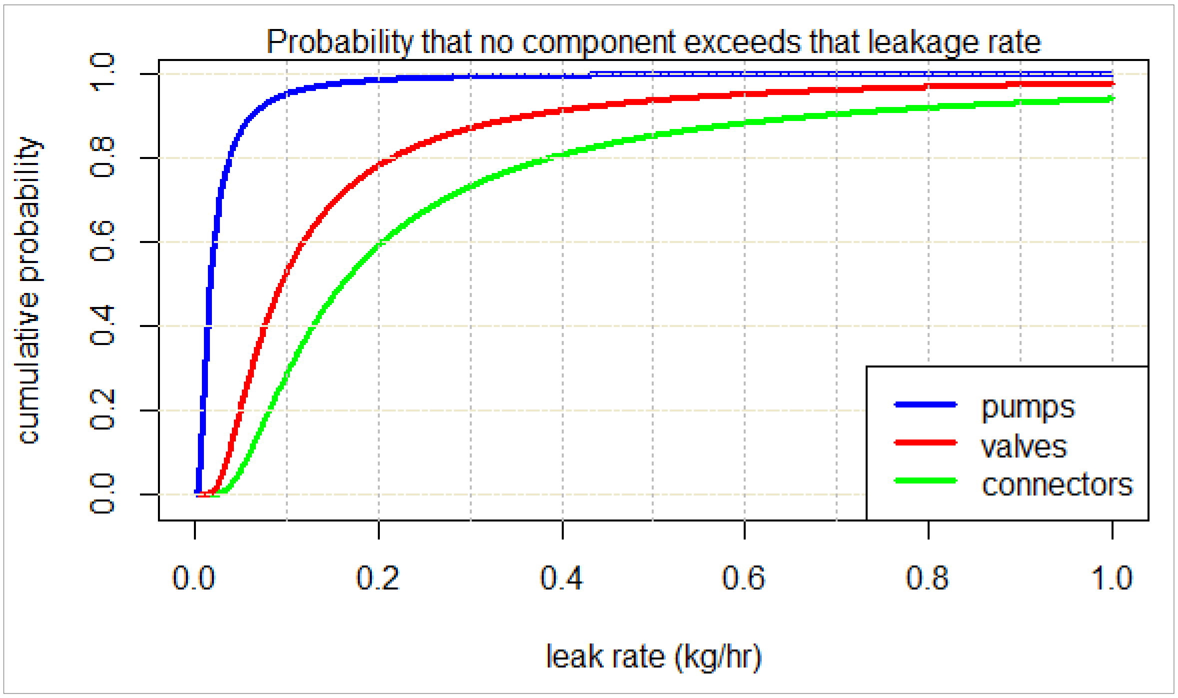

Figure III.66. Cumulative Distribution of Maximum Leakage by Component Type (Pump Seals, Valves, Connectors)

The greatest emissions measured during sampling was 0.016 kg/hour for a valve (Sample C004), 0.002 kg/hour for a connector (Sample A030), and 0.024 kg/hour for a pump seal (Sample D045).

Figure III.66 shows there is a 70 percent chance of one of the petroleum refineries' connectors leaking more than 0.1 kg/hour and a 40 percent chance of the maximum being greater than 0.2 kg/hour. For valves, there is a close to 50 percent chance of leaking more than 0.1 kg/hour and a 20 percent chance of leaking more than 0.2 kg/hour.

Although pump seals were found to leak considerably more than connectors or valves on average, pump seal maximum leakage is lower because there are not nearly as many; there is a less than 10 percent chance of a pump leakage rate greater than 0.1 kg/hour.

Previous studies and the current Study show that screening values are highly skewed. Most screened components have low screening values while less than one percent have screening values greater than 10,000 ppmv.

To understand whether screening results may be biased because of missing large leakers, a comparison of the number of components found with screening values greater than 10,000 ppmv within the Study and in previous studies can be made.

For this comparison, two previous studies are useful: the 1980 EPA Study and the WSPA/API study published in API 337. In the 1980 EPA Study, components were not included in a leak detection and repair program. However, in API 337, screening results from six petroleum refineries (four in California and two in Washington) were evaluated. Of the California petroleum refineries, two (CA-1 and CA-2) had been screening heavy liquid service components within their leak detection and repair program while the other two screened heavy liquid service components in preparation for the 1993 Refinery Study.

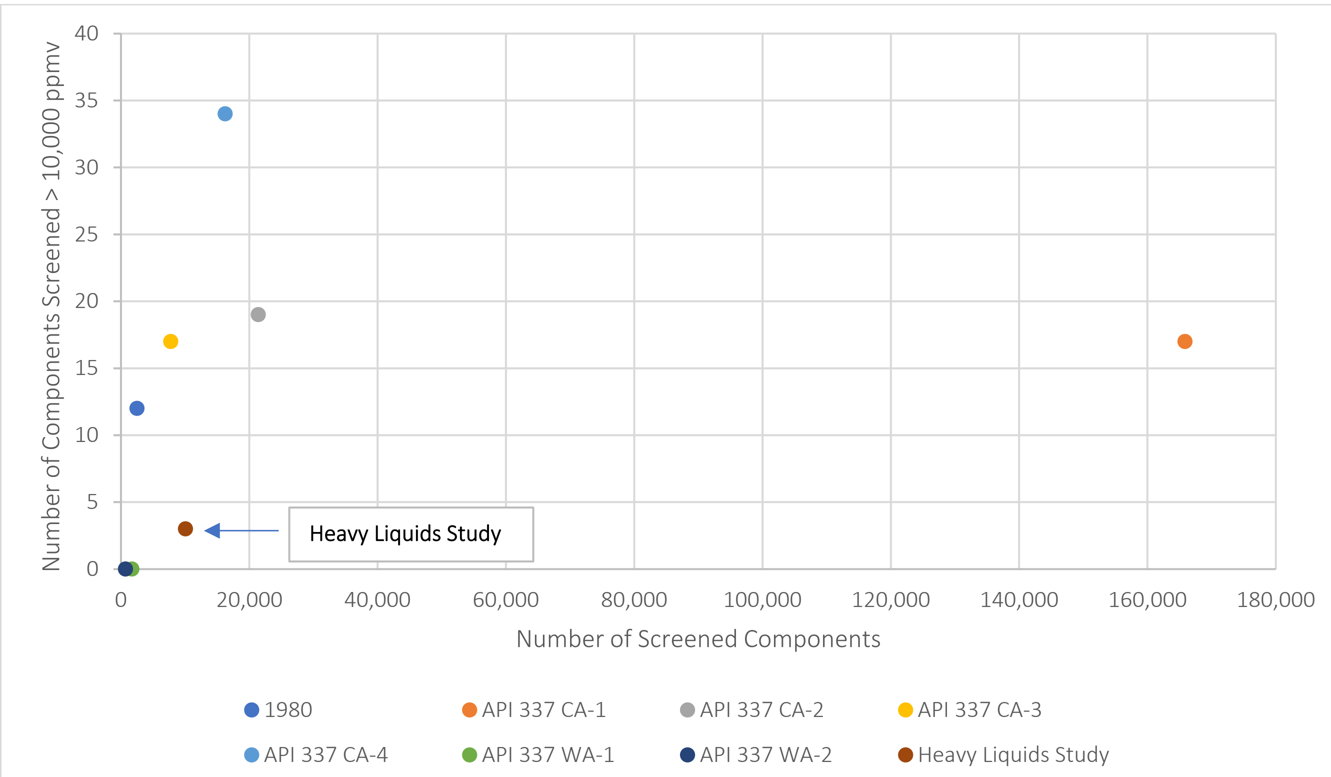

Figure III.67. Comparison of the Number of Components with Screening Values Greater than 10,000 ppmv

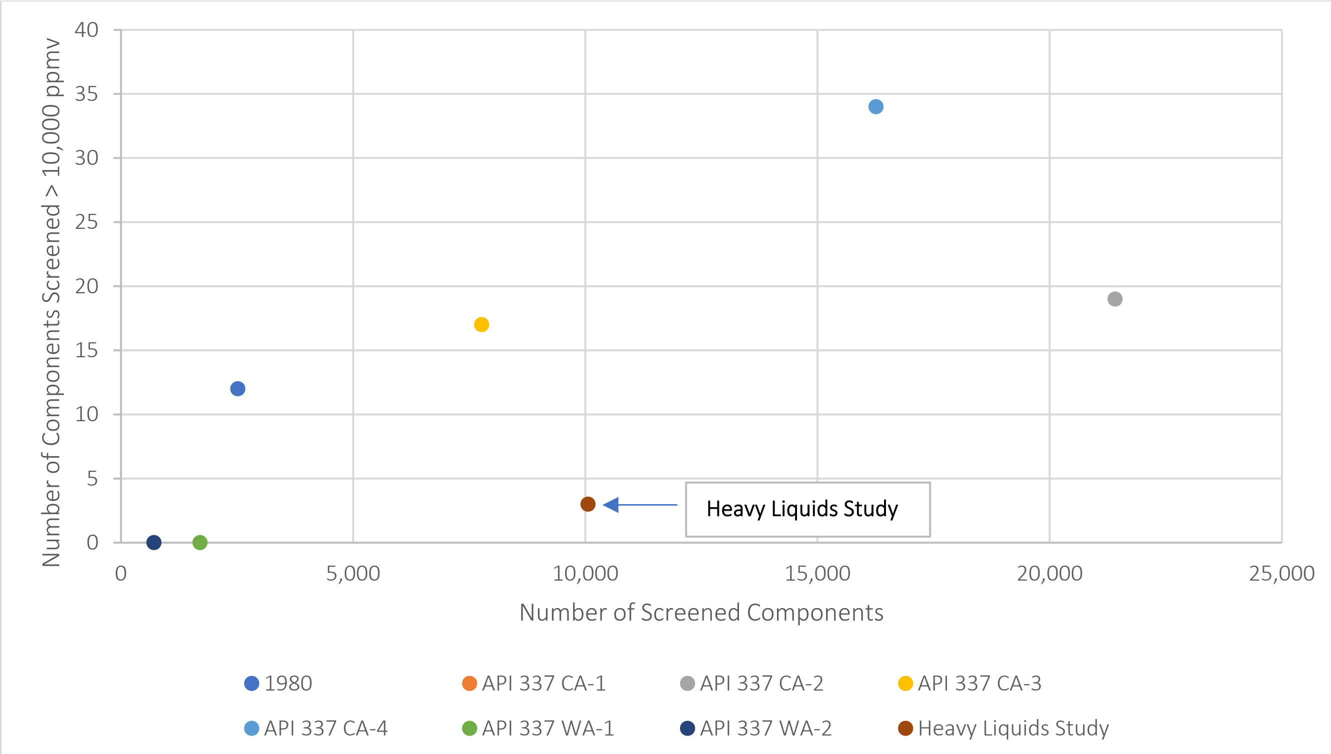

Figure III.68. Comparison of the Number of Components with Screening Values Greater than 10,000 ppmv (Excludes API 337-CA-1)

As shown in **Figure III.67** and **Figure III.68**, the number of components found with screening values greater than 10,000 ppmv in the Heavy Liquids Study was much lower than previous studies.

This difference may be attributed to a difference in emission leaks between the five petroleum refineries during the Study and the other petroleum refineries in previous studies.

However, the three Study components (all valves) with screening values greater than 10,000 ppmv were all found within the same petroleum refinery process unit. The difference in results may also be attributed to the Study design: either the number of screened components was too small to capture the actual distribution of screening results, the selection of process units was insufficiently random, or the total number of process units / areas included within the Study was too small.

III.iv.5.7. Estimated Emission Rates for Various Scenarios

After estimating emissions for screened components, emission rates of connectors, valves, and pump seals for two scenarios were estimated.

Both scenarios exclude steam-quenched pumps and components handling non-process lube oil. The scenarios differ by whether they include or exclude screened components that were within a petroleum refinery's leak detection and repair (LDAR) program.

Emissions estimates by scenario are presented in Table III-73.

Table III-73. Average Emission Factors for Different Categories of Components

Scenario	Connectors (kg/hour/connector)			Valves (kg/hour/valve)			Pump Seals (kg/hour/pump seal)		
	Point Estimate	Confidence Interval 5%	Confidence Interval 95%	Point Estimate	Confidence Interval 5%	Confidence Interval 95%	Point Estimate	Confidence Interval 5%	Confidence Interval 95%
1	8.8-06	6.1E-06	1.51E-05	2.74E-05	1.71E-05	4.29E-05	1.58E-04	7.8E-05	5.84E-04
2	9.4E-06	6.6E-06	1.60E-05	2.84E-05	1.80E-05	4.43E-05	1.18E-04	4.8E-05	4.87E-04

Notes:

Scenario 1 excludes gaseous phase components, steam-quenched pumps, and components handling non-process lube oil

Scenario 2 excludes LDAR components, gaseous phase components, steam-quenched pumps, and components handling non-process lube oil

v. Quality Control

The results of those quality control activities that have recorded qualitative metrics are presented in this section.

The specific quality control activities varied by Study phase: (1) Screening, (2) Sampling, (3) Laboratory, and (4) Analysis.

There were multiple quality assurance and quality control procedures whose efficacy could not be qualitatively measured. For example, training of both screening and sampling personnel in the methodologies to be employed was conducted. However, the training program did not incorporate any pre-training or post-training assessments of personnel. Some indication of the efficacy of the training was noted in field notes of third-party auditors and/or Air District observers.

There were also some quality control procedures that could be qualitatively measured but whose outcome was not recorded and could not be verified.

These are discussed in each of the following sections along with a presentation of the qualitative metrics that were recorded and/or derived from recorded information.

III.v.1. Screening

Quality control procedures for field screening included:

- training of field screening personnel,
- use of an established screening methodology and protocol,
- use of same model screening instruments,
- use of instrument probes and hoses with same specified dimensions,
- pre-monitoring instrument calibrations,
- post-monitoring instrument drift tests,
- use of specified calibration gases for calibrations
- use of standardized field data sheets (see Appendix C-1 for an example), and
- digital photographs of components with leaks above a given threshold.

A metric for determining the efficacy of training and of following the screening methodology does not exist. Field observations of each measurement and whether screening personnel followed the required protocol were not taken. However, third-party auditors (the number and personnel varied by refinery) did observe generally the instrument calibrations, instrument drift checks, and screening measurements. There were times when instrument calibrations, instrument drift tests, and/or screening was done prior to a third-party auditor arriving and observing.

In third-party auditor forms, there were several instances where the auditor noted “the tech was reminded to slow down” or “both technicians were reminded & shown the proper [protocol] speed”, indicating that screening personnel were screening too fast and not following what was stated in training or within the protocol.

Screening instruments, probes, and hoses meeting minimum requirements were verified in the field, but verification was not recorded. The serial numbers of all screening instruments are known and can be used to track measurements to individual screening instruments, if necessary.

All gases used to calibrate and drift test screening instruments were verified as meeting the required specifications for hydrocarbon content and accuracy as well as for not being expired. This information was recorded and verified but is not presented here.

The internal pump flow rates of screening instruments were checked using a rotameter during instrument calibrations to verify minimum flow rates. However, an entry location for this information was not provided on the calibration data sheets so this information was not recorded except for Refinery C, which revised the template calibration data sheet to include data entry location for this information. For Refinery C, screening instrument pump flow rates varied between 1.0 to 2.5 liters per minute and were within the specification of the protocol.

Instrument Calibrations and Drift

To improve the accuracy of measurements, screening instruments were to be calibrated with five gas standards and zero gas prior to each monitoring session and to be drift tested after each monitoring session with results recorded. Most screening occurred in two periods: a morning session and an afternoon session. In these instances, screening instruments were to be calibrated in the morning prior to screening, drift tested at the end of the morning screening session, calibrated again in the afternoon prior to screening, and then drift tested at the end of the afternoon screening session. Some instruments were only used in a morning or afternoon session and therefore a drift test was not required in the session in which screening with that instrument did not occur.

There were multiple instances at Refinery D and Refinery E where instruments were only calibrated in the morning and drift tested at the end of the day.

There were also occasions where drift tests were not performed, or the drift test forms were missing, and a drift test and results could not be verified.

At Refinery C, in several cases, the third-party auditor noted that a screening instrument would not pass (failed) one or more drift tests so was drift tested at the end of the day. In other cases, an instrument was left running overnight before a subsequent drift test was performed. Drift tests for these failed checks were not recorded so it is not known what the actual instrument drift check was. In these cases, the measured drift was treated as unknown.

Where the Air District conducted field screening (all of Refinery A and approximately half of the screening measurements at Refinery B), the same screening instruments were used. However, these instruments differed from those used by each refinery's screening personnel. The number of unique screening instruments used at each refinery varied from seven to twelve instruments.

A summary of the screening instrument drift checks is provided in Table III-74. The table reflects the results of instruments that were drift tested and whose results could be verified. The number of checks reflects the number of unique tests made. The summary information pertains to all instruments that were tested. Summary tables by screening instrument and refinery are provided in Appendix C-2.

Table III-74. Summary Results of Field Screening Instrument Drift Checks

Refinery	Standard (ppmv)	Number of Checks	Average Percent Difference	Minimum Percent Difference	Maximum Percent Difference	Standard Deviation of Percent Difference	95 % Confidence Interval	
							Lower	Upper
A	10	291	-9.5%	-47.7%	100.0%	14.3%	-11.1%	-7.8%
	100	291	-2.7%	-24.8%	51.0%	6.2%	-3.4%	-2.0%
	500	291	-1.8%	-23.5%	55.8%	6.2%	-2.5%	-1.1%
	3,000	291	-1.6%	-21.2%	38.6%	5.4%	-2.2%	-1.0%
	10,000	291	-1.6%	-17.7%	34.0%	5.0%	-2.1%	-1.0%
B	10	136	-7.4%	-33.7%	22.0%	9.3%	-9.0%	-5.9%
	100	136	-3.3%	-15.3%	9.5%	4.3%	-4.0%	-2.6%
	500	136	-2.3%	-13.8%	11.3%	4.0%	-2.9%	-1.6%
	3,000	136	-2.9%	-71.3%	8.0%	6.9%	-4.1%	-1.8%
	10,000	136	-2.0%	-10.9%	5.6%	2.8%	-2.4%	-1.5%
C	10	103	-4.8%	-20.0%	24.0%	8.8%	-6.6%	-3.1%
	100	103	-1.6%	-11.1%	11.7%	5.1%	-2.6%	-0.6%
	500	103	-1.5%	-9.8%	14.1%	5.1%	-2.5%	-0.5%
	3,000	103	-1.4%	-11.1%	14.0%	4.7%	-2.3%	-0.4%
	10,000	103	-1.0%	-16.2%	11.7%	4.7%	-2.0%	-0.1%
D	10	127	-2.4%	-33.0%	56.4%	14.8%	-5.0%	0.2%
	100	127	-2.3%	-9.7%	9.7%	3.8%	-3.0%	-1.6%
	500	127	2.3%	-12.3%	513.0%	45.8%	-5.8%	10.3%
	3,000	127	-0.1%	-12.6%	51.9%	7.8%	-1.5%	1.3%
	10,000	127	-1.0%	-24.3%	9.1%	3.4%	-1.6%	-0.4%
E	10	94	-13.2%	-34.2%	16.2%	9.4%	-15.1%	-11.2%
	100	94	-5.3%	-19.2%	7.7%	5.0%	-6.3%	-4.3%
	500	94	-4.7%	-17.6%	6.3%	4.3%	-5.6%	-3.9%
	3,000	94	-4.9%	-39.1%	9.0%	6.2%	-6.2%	-3.6%
	10,000	94	-2.9%	-16.5%	5.9%	3.7%	-3.7%	-2.2%

As shown in Table III-74, the average percent drift varied the most for the 10 ppmv standard and in every case the average drift was negative. Except for the 500 ppmv standard at Refinery D, the entire confidence interval for each standard was negative suggesting a negative bias in screening results.

For Refinery D, there was a maximum drift reading of 513 percent for the 500 ppmv standard. From the field calibration sheet for this test, it appeared that the 3,000 ppmv standard was used during the 500 ppmv drift test. If so, the test for this standard would not have been valid. However, this could not be verified.

Plots of the average drift percentage by instrument, standard, and refinery are shown in Figure III.69, Figure III.70, Figure III.71, Figure III.72, and Figure III.73.

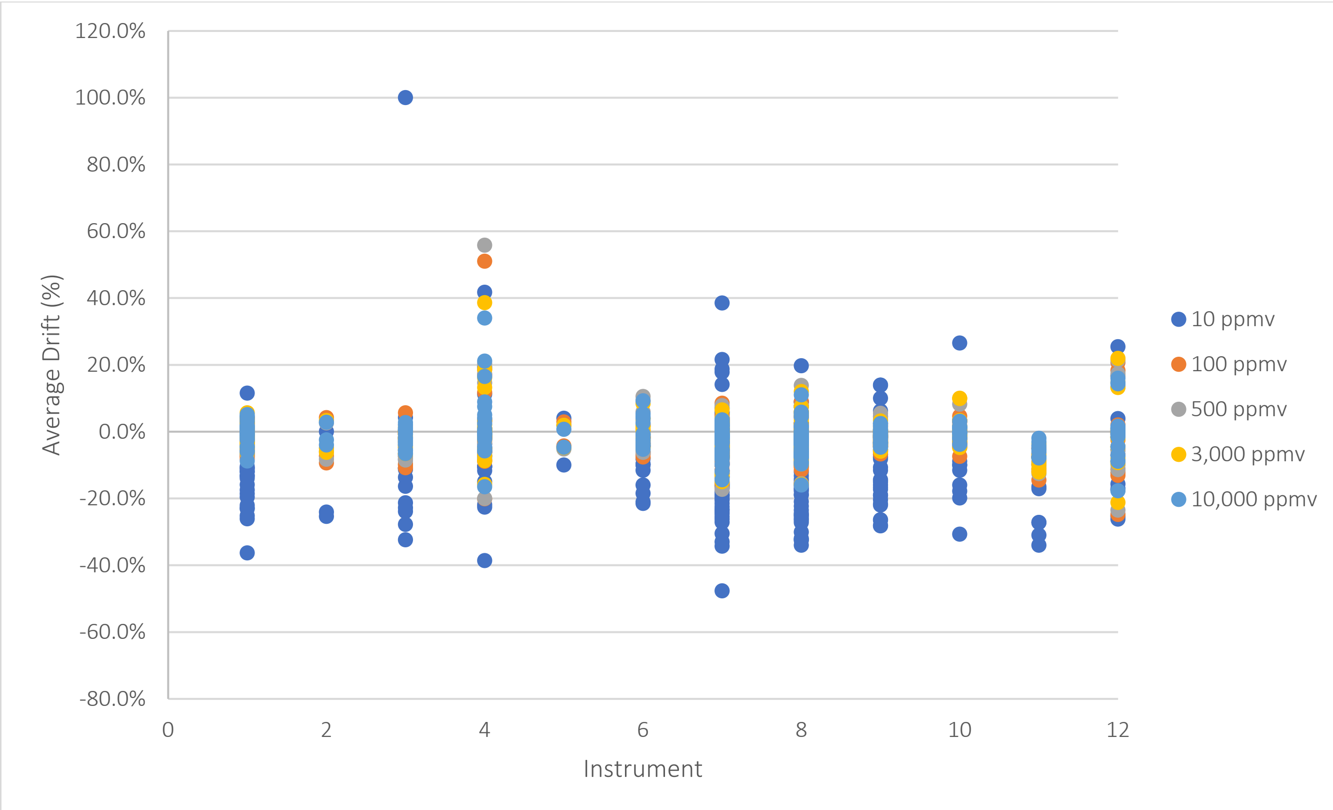

Figure III.69. *Average Drift by Calibration Gas of Screening Instruments Used at Refinery A.*

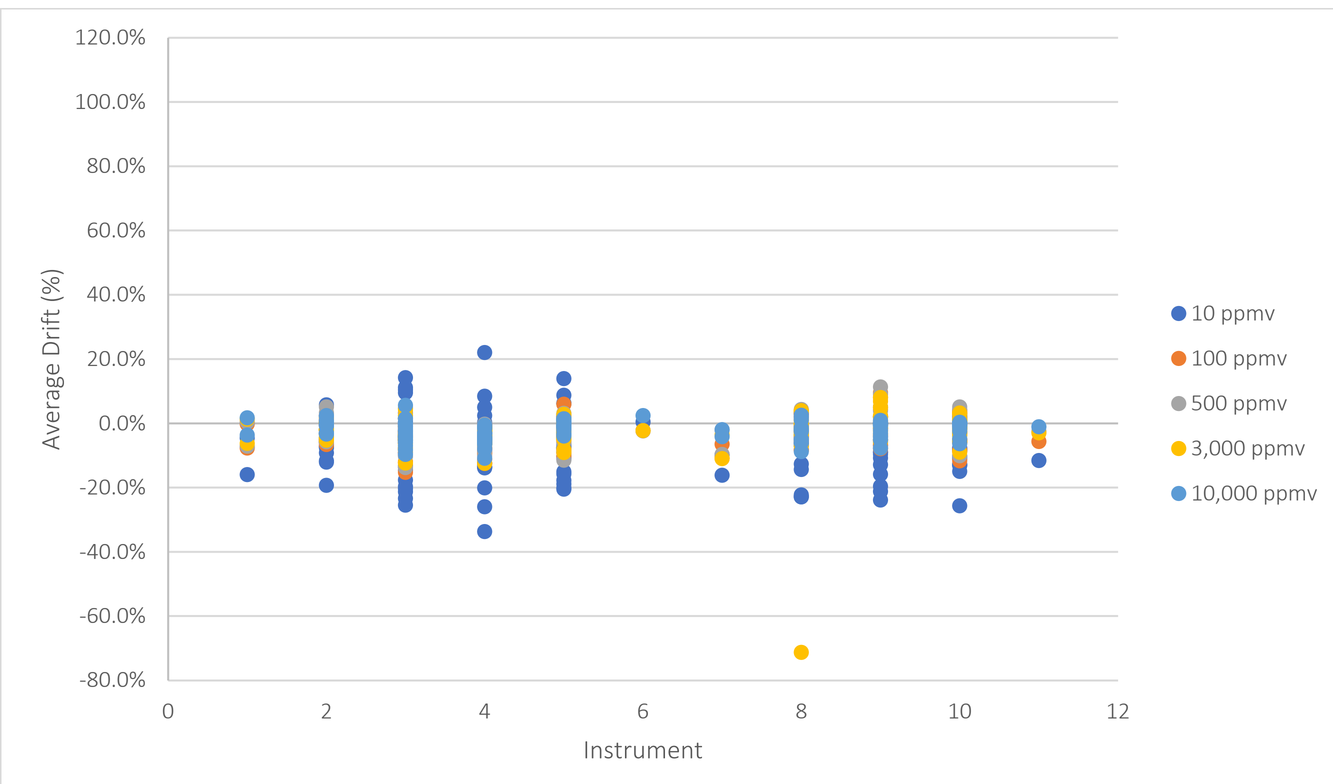

Figure III.70. *Average Drift by Calibration Gas of Screening Instruments Used at Refinery B.*

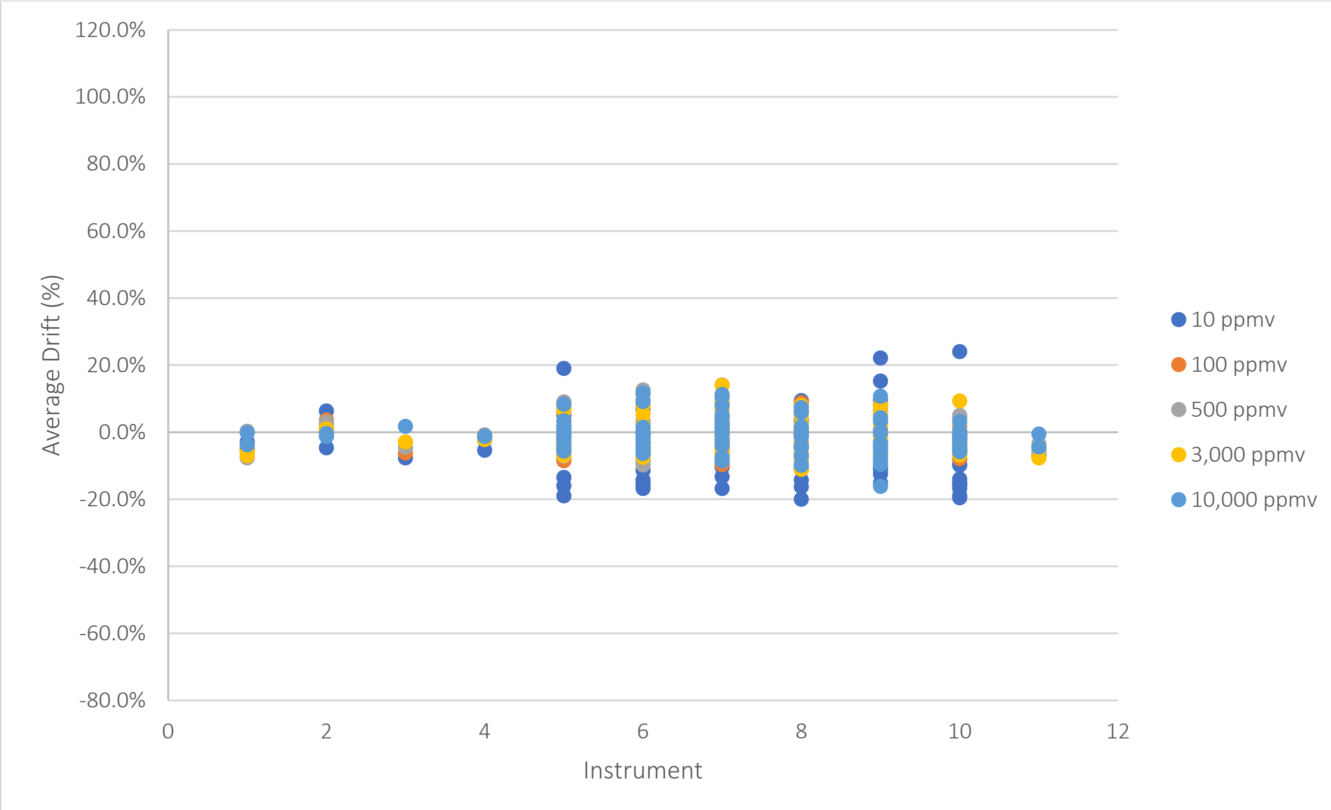

Figure III.71. Average Drift by Calibration Gas of Screening Instruments Used at Refinery C.

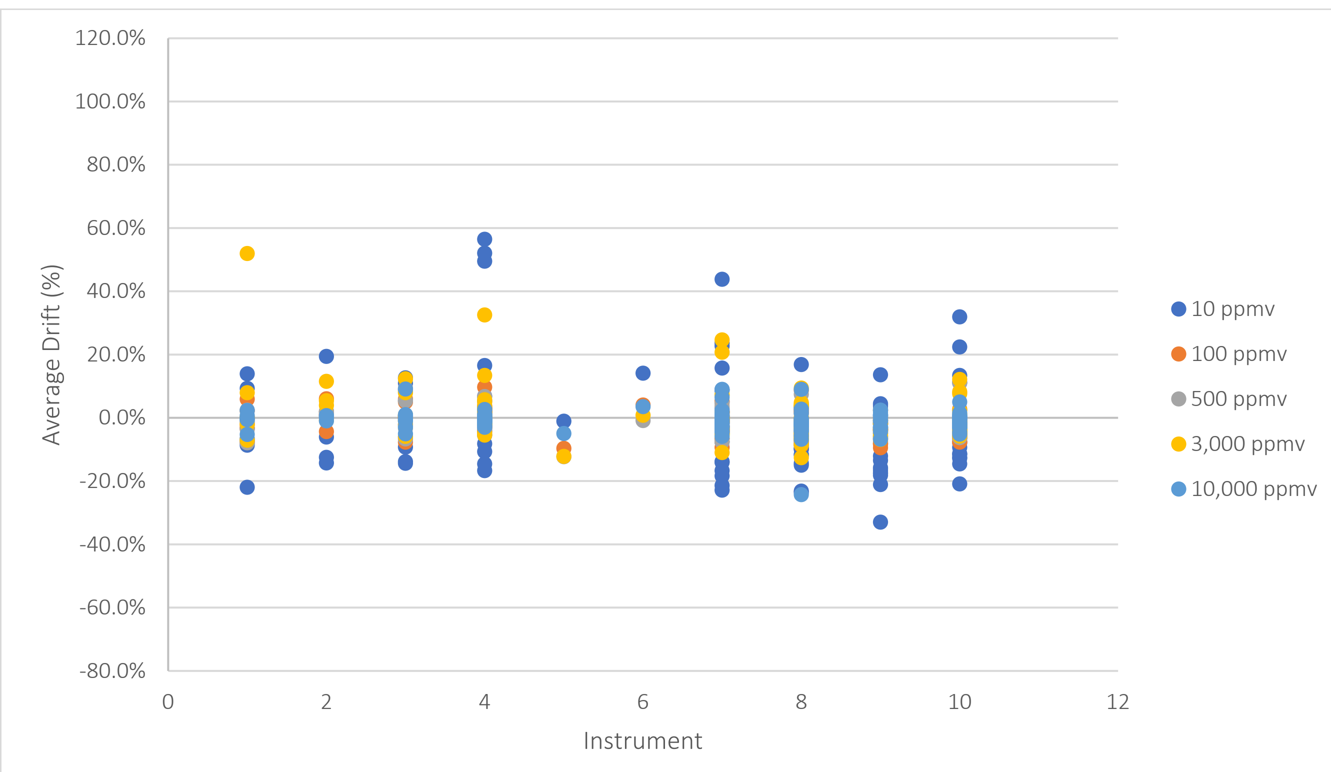

Figure III.72. Average Drift by Calibration Gas of Screening Instruments Used at Refinery D.

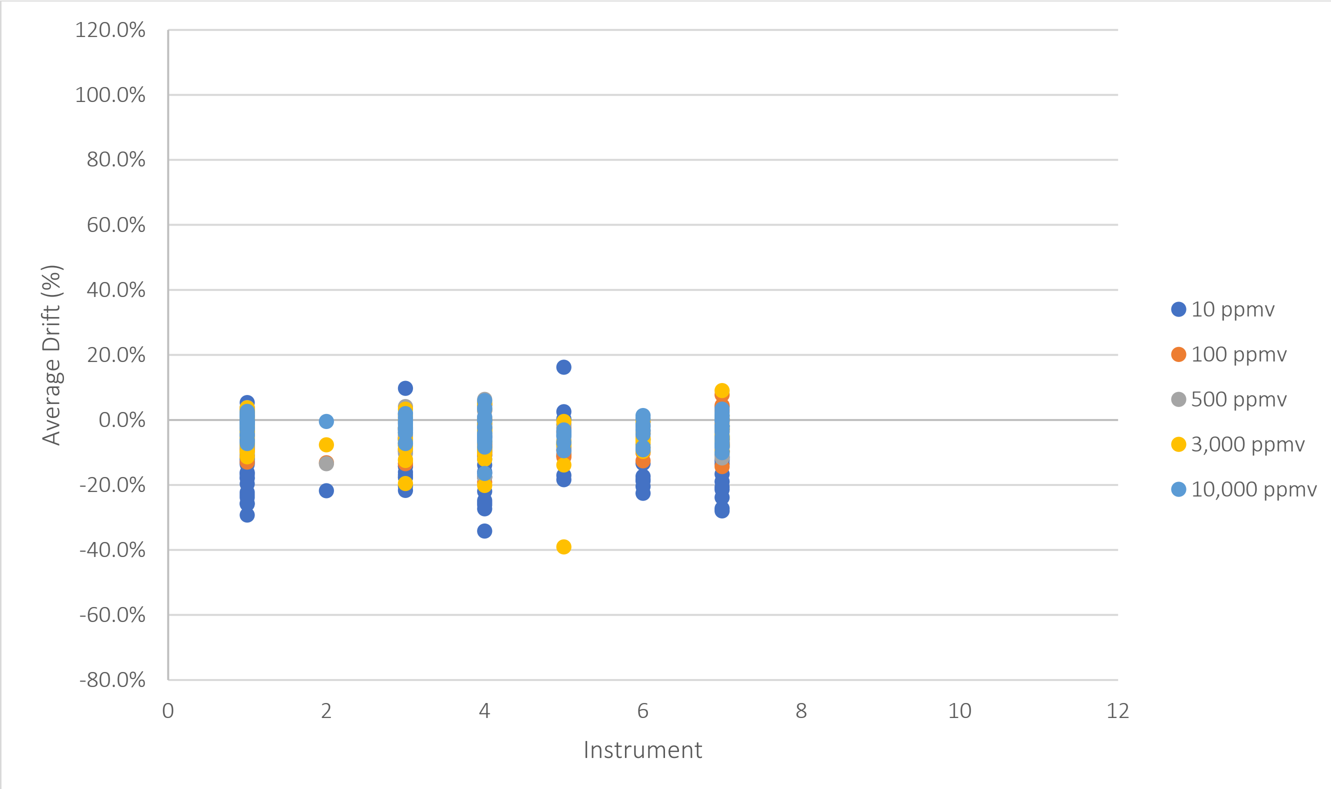

Figure III.73. Average Drift by Calibration Gas of Screening Instruments Used at Refinery E.

As indicated in the plots, the dispersion in drift varied by petroleum refinery and screening instrument.

Number of Screening Measurements Potentially Impacted by Drift

Prior to initiating screening at Refinery A, drift targets for the standard were established to understand what would be acceptable and whether re-screening of components was required.

A drift target of ± 10 percent for all standards was established. However, during screening at Refinery A, it was determined that meeting this target for the 10 ppmv standard was too difficult and this target was increased to ± 25 percent for the 10 ppmv standard while the ± 10 percent target was maintained for the other standards.

In addition, as screened components could not be readily re-located (except for Refinery C that had affixed physical identification tags on all heavy liquid service components), components were not re-screened if an instrument did not meet a drift target. Rather, additional components beyond the targeted number of Study components were screened at each refinery to meet the target number in case some components were excluded after an analysis of drift.

The percentage and number of screening measurements whose screening instrument met a drift target varies by both the target and gas standard. The following tables provide an indication of the number of components that would be excluded if a drift target were used to exclude components from the Study.

Table III-75. *Percentage of Total Screening Measurements whose Screening Instrument Met Drift Target*

Drift Target	Met Drift Target for All Span Gases (percentage of total)				
(10 ppmv / All Others)	Refinery A	Refinery B	Refinery C	Refinery D	Refinery E
± 25% / ± 10 %	78%	90%	85%	83%	75%
± 25% / ± 12.5 %	79%	91%	89%	88%	85%

III.v.2. Mass Emissions Sampling

Several quality assurance activities and quality control procedures were employed during sampling including:

- use of same model screening instrument for taking pre-bag measurements,
- equipment (screening instrument, sampling pump) calibrations,
- conducting drift tests of screening instruments,
- use of standard gases for both calibration and drift tests,
- checking screening instrument internal pump flow rate,
- minimum flow rates (dry gay meter, sample pumps, sample train),
- minimum sample volume,
- minimum sample bag vacuum,
- use of same sample media,
- use of clean sample lines,
- taking background samples at each petroleum refinery,
- repeated sampling,
- duplicate sampling,
- training of sampling personnel,
- use of standardized field data forms (see Appendix C-1 for an example),
- field spike recovery studies, and
- taking digital photographs of sampled components pre-sample, during sampling, and post-sampling.

Minimum Sampling Specifications

Quality assurance targets for minimum sampling specifications were outlined prior to sampling. These included:

- a minimum sample bag vacuum (0.001 to 0.1 inches H_2O),
- minimum sample train flow rate (1.0 liters per minute),
- minimum sample volume (12.0 liters), and
- minimum dry gas meter flow rate (5.0 liters per minute).

Sampling ranges for each of the above items by refinery are provided in Table III-82 and Table III-83.

***Table III-82**. Sampling Ranges of Sample Vacuum Pressure and Sorbent Media by Refinery*

Refinery	Initial Bag Vacuum [1] (Inches H_2O)		Bag Vacuum [2] (Inches H_2O)		Sample Flow @ STP [3] (Liters/minute)		Sample Run Time (minutes)		Sample Volume @ STP [3] (Liters)	
	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max
A	N/A [4]	N/A [4]	0.001	0.15	0.28	0.32	40.00	51.00	11.32	15.74
B	0.001	2.00	0.001	0.25	0.89	1.01	12.00	14.00	10.86	13.77
C	0.01	0.12	0.01	0.13	0.89	1.01	13.00	14.00	11.60	13.45
D	0.001	0.20	0.001	0.12	0.90	1.06	12.00	13.00	11.35	13.70
E	0.01	0.11	0.01	2.00	0.88	1.03	13.00	13.00	11.45	13.34

Notes:

1. The sample tent (bag) vacuum prior to initiating sampling

2. The sample bag vacuum after sampling began
3. STP = Standard temperature (21 degrees Celsius), standard pressure (760 mm Hg)
4. Initial bag vacuum at Refinery A was not recorded and is therefore, unknown

Table III-83. Dry Gas Meter Sampling Ranges by Refinery

Refinery	Dry Gas Meter Flow @ STP (3) (Liters/minute)		Dry Gas Meter Volume @ STP (3) (Liters)		Total Run Volume @ STP (3) (Liters)	
	Min	Max	Min	Max	Min	Max
A	3.66	8.08	153.56	369.88	166.89	385.61
B	1.09	7.64	13.10	91.71	35.88	116.87
C	0.65	6.83	8.48	88.78	33.10	115.12
D	1.61	7.14	20.92	92.78	48.22	119.17
E	5.16	6.92	67.11	89.94	91.12	115.30

Notes:
1. STP = Standard temperature (21 degrees Celsius), standard pressure (760 mm Hg)

The minimum bag vacuum requirement (0.001 inches H_2O) was met by all samples. However, a pressure gauge with a resolution of 0.005 inches H_2O was used in sampling. It is not clear how lower measurements were identified.

The minimum sampling rate of 1.0 liters per minute was not met at Refinery A or the other refineries but was within 11 percent for all but Refinery A.

A minimum sample volume of 12.0 liters was not met in several cases but was within 10 percent.

There were nine components where the dry gas meter flow did not meet the minimum flow rate requirement (5 liters/minute): A013, B01, C09, D09, D011, D025, D027, D045, and D052.

Field Spike Recovery Studies

Field spike recovery studies were conducted at each of the five refineries. Spikes with known amounts of specified compounds were introduced in the field either sequentially or in parallel with sampling of a component.

Summaries of these results are listed in Table III-84.

Table III-84. Field Spike Recovery Sample Results

			Recovery Percentage (%) by Compound (by carbon number)																					
Refinery	*Sample*	*Spike*	C_5	C_6	C_7	C_8	C_9	C_{10}	C_{11}	C_{12}	C_{13}	C_{14}	C_{15}	C_{16}	C_{17}	C_{18}	C_{19}	C_{20}	C_{21}	C_{22}	C_{23}	C_{24}	Minimum	Maximum

Replicate Sampling

Replicate samples were taken with each primary sample. Replicate samples at Refinery A and some at Refinery B were taken sequentially after the primary sample using the primary sampling line (there was a secondary sampling line that was used for field spikes). Sequential sampling introduced an additional variable (operational changes over time) as a possible cause for potential differences between primary and replicate sample results.

Replicate sampling at the other petroleum refineries were taken in parallel using a secondary sample line at the same time as the primary sample.

A comparison of primary sample results with replicate sample results can be made by plotting the results against each other as shown in Figure III.79.

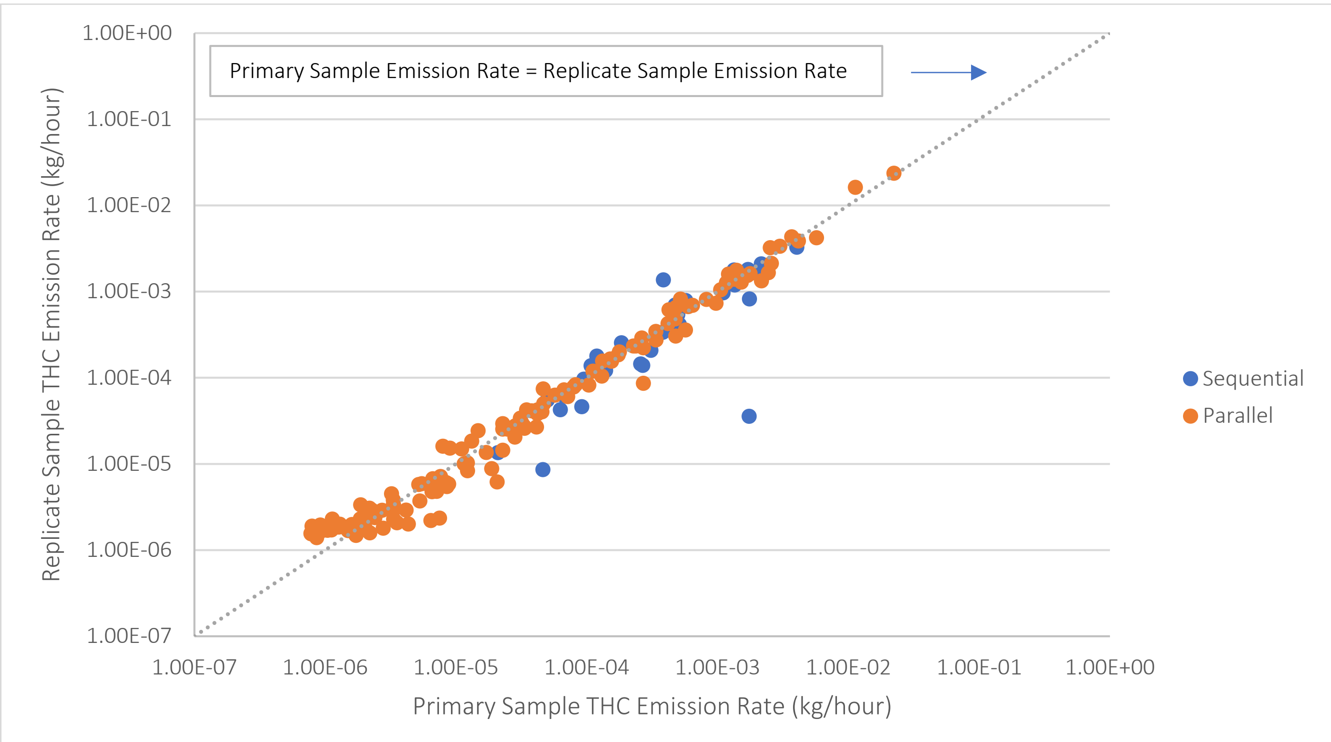

Figure III.79. Primary versus Replicate Sample Results for Both Sequential and Parallel Replicate Sampling

As demonstrated in Figure III.79, measurements of replicate samples taken sequentially after primary samples show a greater separation from primary sample measurements. There was one component (A09) whose primary and replicate sample results differed by two orders of magnitude and whose relative difference (primary results – replicate results / average of the two) was 192 percent. For this component, approximately 75 minutes elapsed between the start of primary sampling and the start of replicate sampling.

The relative difference between each primary and replicate sample pair is plotted with the average of the two samples in Figure III.80 . A difference of zero would indicate the primary sample and replicate sample results were approximately equal.

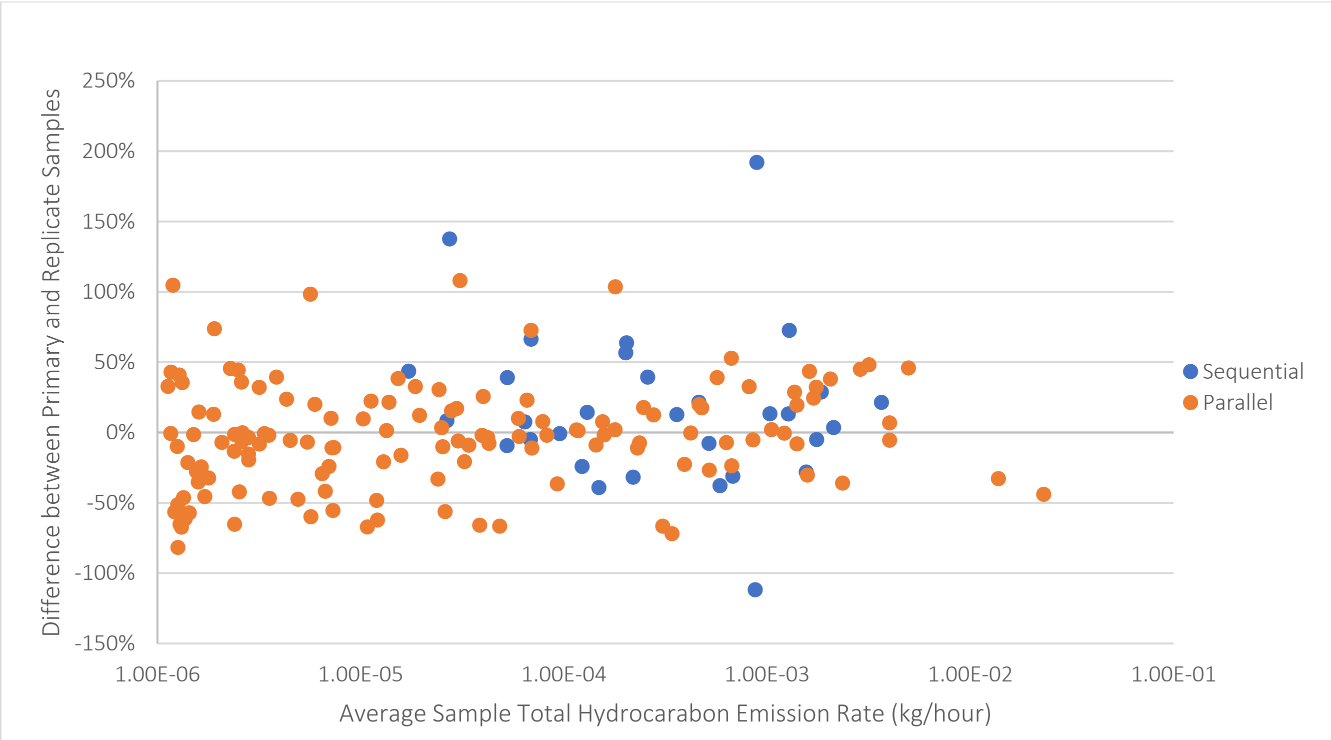

Figure III.80. Average of Primary and Replicate Sample Results versus Percent Differences of Primary and Replicate Samples.

Most primary and replicate sample results were within ± 50 percent of each other.

The two data points (the uppermost and lowermost data points) with the largest difference had an average emission rate of 1.00E-03 kg/hour and a differed by 192 percent and –112 percent. Replicate sampling in both instances (Sample A09 and A017) was done sequentially.

Repeated Sampling

At least one component at each petroleum refinery had repeated sampling done.

There were eleven components that were sampled multiple times (not including replicate sampling). These components were: A-901, A-1050, A-1259, A-1730, B-0551, B-0632, B-0818, B-1124, C-21210, D-0596, and E-2200.

Except for Component A-1050, each component was sampled twice with each sampling having both a primary and replicate sample.

Component A-1050 was sampled four times.

The following figure plots the average of the primary and replicate samples for each repeated sample pair against each other.

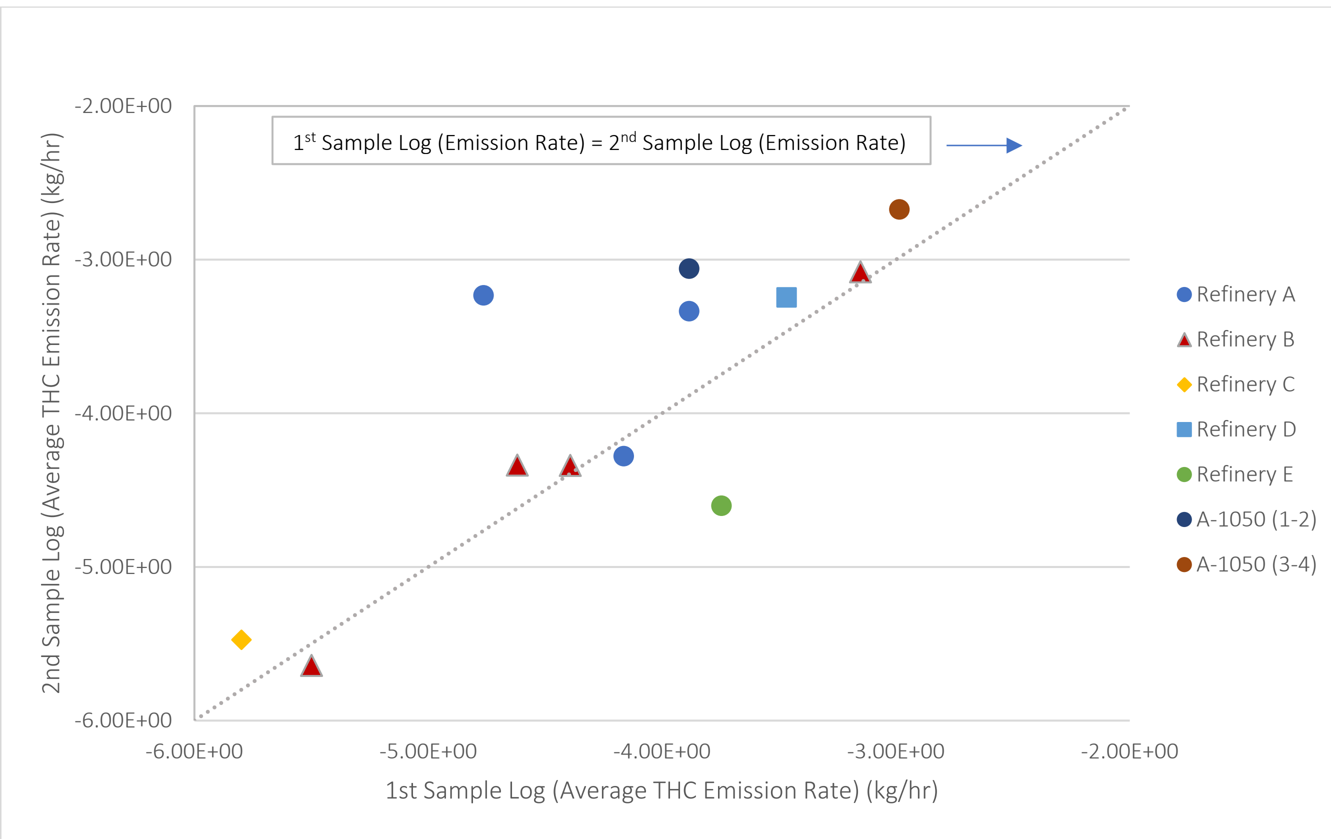

Figure III.81. Comparison of results of repeated sampling

Repeated sample results at Refinery B showed close alignment while results for components A-1730 and E-2200 had the largest difference between sample pairs.

Component A-1050 was sampled four times (each with a primary and replicate sample) with three and four days in between sampling.

Plotting the pre-bag screening values with the averages of the primary and replicate samples for each of the four repeated samples of component A-1050 shows an increase in the average sample results with each repeated sample (see **Figure III.82**).

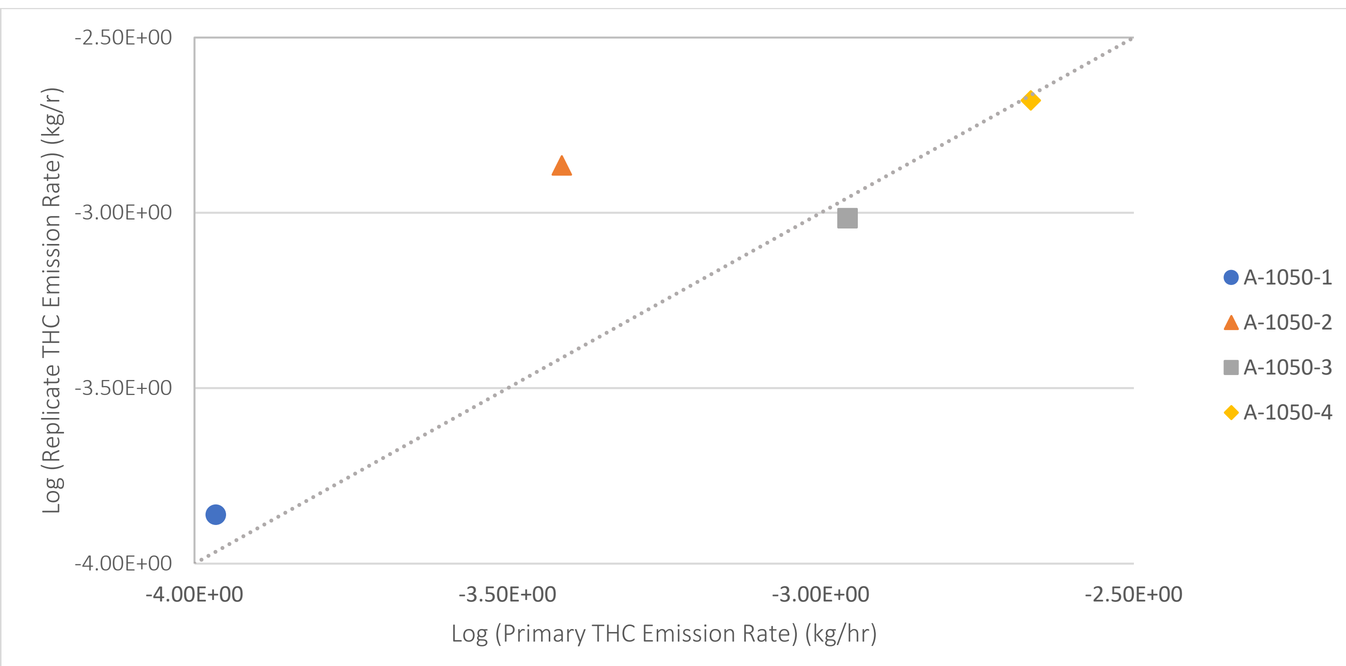

Figure III.83*. Primary versus replicate sample results of repeated sampling of component A-1050.*

III.v.3. Laboratory

The third-party laboratory (Enthalpy Analytical, LLC) performed several quality control activities as stipulated by the test methods employed as well as by the laboratory's own internal standards.

For each set of spikes prepared for field spike recovery studies, the laboratory retained two spikes for use as laboratory control samples. The results of laboratory control samples can ascertain the laboratory's ability to recover known amounts of compounds.

Laboratory recoveries of C_5 to C_{30} compounds varied between 28 percent (C_5 n-Pentane) to 191 percent (C_{22}, C_{23}, and C_{24} compounds). The minimum and maximum recoveries by refinery are provided in Table III-85. Detailed recoveries by laboratory control sample are provided in Appendix C-2.

Table III-85. Laboratory Control Sample Recoveries Summary

Refinery	Count of Laboratory Control Samples	Minimum (%)	Maximum (%)
Refinery A	17	28	191
Refinery B	7	78	163
Refinery C	9	71	128
Refinery D	12	76	143
Refinery E	9	64	130
All	54	28	191

For selected component samples, the laboratory prepared an additional aliquot of the sample for processing, testing, and analysis independent of the initial sample aliquot. A comparison of results with the initial aliquot results provides an indication of the laboratory's precision and repeatability.

A summary of laboratory duplicates results by refinery is outlined in Table III-86.

Table III-86. Laboratory Duplicates Percent Difference Ranges for Compounds Detected Above Detection Level by Refinery

Refinery	Count of Lab Duplicate Samples	Percent Difference of Detects (1)	
		Minimum (%)	Maximum (%)
Refinery A	13	0.01	49
Refinery B	8	0.05	14
Refinery C	7	0.16	5
Refinery D	13	0.03	43
Refinery E	10	0.09	29
All	51	0.01	49

Notes:
1. Range of percentage difference between duplicate and sample for where the compound of interest was detected above a detection level.

A summary of laboratory results by compound is listed in Table III-87.

Table III-87. *Laboratory Duplicates Percent Difference Ranges for Compounds Detected Above Detection Level by Compound*

Compound	Count of Duplicates	Count of Detects [1]	Percent Difference of Detects [2]	
			Minimum (%)	Maximum (%)
n-Pentane (C_5)	51	8	0.2	24.8
n-Hexane (C_6)	51	10	2.1	47.2
n-Heptane (C_7)	51	10	0.1	28.9
n-Octane (C_8)	51	20	0.03	15.6
n-Nonane (C_9)	51	23	0.02	29.8

n-Tridecane (C_{13})	51	29	0.1	11.5
n-Tetradecane (C_{14})	51	30	0.2	11.6
n-Pentadecane (C_{15})	51	27	0.01	11.7
n-Hexadecane (C_{16})	51	19	0.2	28.9
n-Heptadecane (C_{17})	51	16	0.2	24.8
n-Octadecane (C_{18})	51	12	0.3	10.0
n-Nonadecane (C_{19})	51	11	0.6	12.3
n-Eicosane (C_{20})	51	11	0.1	14.7
n-Heneicosane (C_{21})	51	8	0.9	17.9
n-Docosane (C_{22})	51	10	0.3	34.0
n-Tricosane (C_{23})	51	8	0.3	22.8
n-Tetracosane (C_{24})	51	8	0.8	26.2
n-Pentacosane (C_{25})	6	2	7.5	29.5
n-Hexacosane (C_{26})	6	2	7.0	33.0
n-Heptacosane (C_{27})	6	2	6.0	36.9
n-Octacosane (C_{28})	6	1	40.8	40.8
n-Nonacosane (C_{29})	6	1	45.9	45.9
n-Triacotane (C_{30})	6	1	49.0	49.0

Notes:

1. Count of duplicate samples where the compound of interest was detected above a detect level.
2. Range of percentage difference between duplicate and sample for where the compound of interest was detected above a detection level.

IV. Discussion

In this section, the findings outlined in the Results Section and relevant appendices are discussed.

i. Study Coverage

The Study investigated emissions from components by multiple categories including by petroleum refinery, component type, process unit, stream material, operating temperature (using external component temperature as a surrogate), operating pressure, as well as several others.

Petroleum Refinery

Components at all five Bay Area petroleum refineries were included within the Study. Components of similar type, subtype, stream material, and operating conditions were evaluated at each petroleum refinery. Where differences existed between the five petroleum refineries was in the types of process units / areas where connectors and valves were screened, screening personnel, as well as the types of components that were sampled for mass emissions measurements.

Component Types

At the initiation of the Study, four component types were identified for inclusion within the Study:

- pump seals,
- valves,
- connectors, and
- pressure relief valves that relieved to atmosphere.

Almost all accessible pumps and pump seals were screened as part of the Study while approximately six percent of the total estimated valve population and approximately two percent of the total estimated connector population was screened.

Some pressure relief devices including pressure relief valves were screened. However, these components did not relieve to atmosphere and were categorized as connectors.

Because of the lack of atmospheric relieving pressure relief valves that were evaluated within the Study, there is insufficient information to understand or derive an average emission rate for pressure relief valves that handle heavy liquid materials and relieve to atmosphere.

Process Units

Since it was deemed practical and feasible to screen all pump seals at each petroleum refinery, almost all process units are covered within the Study.

However, valves and non-pump associated connectors were only evaluated within selected process units.

A maximum number of two process units per petroleum refinery was initially targeted to study emissions from connectors and valves. The number of process units was expanded until the targeted number of screened components was met.

The distribution of screening values was found to vary by process unit / area (see Figure III.10). However, as shown in Table III-72, non-pump associated connectors and valves were screened in only a fraction of the total number of process units / areas.

Because of this, results may differ if more or different process units are studied.

ii. Screening

Other than the specifics of a component, screening results are dependent upon:

- screening instrument response,
- screening distance,
- screening time,
- screening pace, and
- screening instrument drift.

Screening Instrument Response

Screening instrument response (the difference between the measured concentration and the actual concentration of a leak) was found to vary depending upon the stream material, the leak magnitude, and the temperature of the stream material.

In general, screening instruments responded quicker to leaks from components handling lighter materials (kerosene, diesel, jet), at lower temperatures, with large screening values.

Leaks from components handling heavier, hotter streams had slower instrument responses. In addition, after screening such components, screening instruments took longer to return to background levels.

Therefore, if insufficient time was spent screening a leak, measured screening values may be lower than actual. If screening instruments were not permitted to return to background levels before a subsequent measurement, measured screening values may be higher than actual.

Approximately 94 percent of screening values were less than 10 ppmv. Therefore, there is a greater potential impact on average emission rates from screening too fast and not measuring the actual leak concentration than not allowing screening instruments to return to background levels.

Although not investigated, one potential explanation for the observed difference in screening instrument response to different process streams and process stream temperatures may be gas/vapor phase streams condensing within the screening instrument (probe, probe filter, tubing, etc.).

Screening Distance

Screening distance was found in several previous studies (1980 EPA Study, API Publication Number 332, etc.) to have a significant impact on the measured screening value. The differences between screening values when screening at the surface versus at 1 centimeter from the surface could be three to four times higher, depending on the instrument.

Within API Publication Number 332, the Western States Petroleum Association found results that indicated a screening value of 10,000 ppmv at the surface would correspond to a screening value of less than 3,000 ppmv when screened at one centimeter from the surface with an FID screening instrument (the same type used in the Study). If components were screened at greater distances from the surface, measured screening values would be lower.

The Study required screening components at the surface of the component where leaks would occur. However, unlike the 1980 EPA Study where an offset device was used to ensure screening values were taken at one centimeter, the Study did not include a mechanism for determining the actual distance a component was screened at if not at the surface.

The screening field notes include three known areas where components were not screened at the surface:

- where insulation or scaffolding prevented access,
- where a grate, metal plate, or guard was surrounding a pump seal shaft, or
- where a pump seal had steam injection,

If a component could not be screened at all because of insulation, it was noted in field screening sheets. However, there were multiple entries where components could not be screened completely.

When a grate, plate, or guard is present; the typical grate or guard surrounds a pump rotating shaft at an offset distance of several inches with some pump shafts having a grate or guard at eight or ten inches offset. In these instances, because screening was not conducted at the surface of the seal, measured screening values are expected to be much lower than would have otherwise been measured.

For steam injected pump seals, some pumps were found to have high steam injection rates where steam was billowing out from the seal, which prevented screening at a distance any closer than several feet away. One such pump was found to have a screening value of 760 ppmv at over a foot or more of distance. Because of the distance at which the screening measurement was taken and the findings of previous studies, a screening value of well over 10,000 ppmv was expected. This pump was also leaking a steady stream of hydrocarbons into a pool that collected at the base of the pump.

Screening Time

For a given leak, the maximum leak concentration is expected to remain relatively constant within a short duration. Screening time is not expected to impact the actual leak concentration but rather what is measured. Screening a component for longer will not change the actual leak concentration (i.e., screening measurements will not exceed actual values) but screening too quickly is likely to result in a measurement that does not reflect the actual leak concentration.

Overall, screening conducted by refinery personnel at Refineries B, C, D, and E was quicker than screening conducted by Air District personnel at Refinery A and Refinery B. Some of the difference may be attributed the differences in screening between components in gas and light liquid service, in which Air District personnel have most experience, and in components in heavy liquid service.

Screening Pace

Screening pace differs from screening time in that screening pace accounts for the size of a component. Larger components will require more time to screen and detect the location of a maximum leak. Screening pace varied by refinery with screening pace found to be longer at Refinery A and Refinery B where the Air District conducted screening. Because of the variation in stream materials, stream temperatures, and leak magnitude; screening instrument response varied sometimes from process line to process line as components in different streams and temperatures were screened.

Prior to screening at Refinery A, the Air District evaluated screening instrument response times to several different materials at different temperatures (see Table II-11) and found that screening instrument response times varied by material and temperature. This was also found during screening at Refinery A. During training, all screening personnel were instructed that screening pace would need to be adjusted based on field conditions, but that screening should not occur any faster than four seconds per inch of component surface screened. An attempt was made to determine if there was a minimum screening pace per stream material and temperature using the screened data set, but it was difficult to differentiate a minimum screening pace based on screening instrument response from the potential impact of screening personnel (whether they were screening too fast or screening longer than necessary).

To understand and determine a screening pace based on stream material and stream temperature of a component, the work carried out and depicted in Table II-11 would need to be expanded.

Screening Drift

Screening instruments were found to experience significant drift. Individual screening instruments at each refinery experienced varying levels of drift (see Figure III.69 through Figure III.73 and Appendix C-2).

However, except for the 500 ppmv standard at Refinery D, the entire confidence interval for each standard on average was negative suggesting a negative bias in screening results.

Prior to screening, maximum drift targets were established as ± 10 percent for each standard. While screening at Refinery A, the maximum drift target for the 10 ppmv calibration gas was increased to ± 25 percent.

There are several potential ways to address the negative bias in screening results. One way is to simply exclude components that did not meet a maximum drift criterion. The number of potential components that would be excluded by varying maximum drift criteria is shown in Table III-76, Table III-79, and Table III-81.

As shown in Table III-76, excluding components that were screened with an instrument that did not pass the maximum drift criterion for all calibration gases would result in discarding up to 1,282 screening measurements (approximately 12 percent of all screening measurements).

Another solution would be to adjust screening values by the amount of drift experienced either using an average applied to all screening values or the drift experienced by the screening instrument used to take a measurement. The first approach would be less accurate than the second. However, there were often dozens of screening measurements taken with a screening instrument in between when an instrument was calibrated and when it was drift tested. The first measurement after calibration may have caused an instrument to drift or the last measurement may have caused it. Adjusting all screening measurements by the drift measured at the end of a screening session was found to increase average emission rates by between one and nine percent, depending upon the component type.

However, the screening instruments used to take pre-bag screening measurements used in the regression analysis also experienced similar drift. Rather than adjust both the pre-bag screening measurements and the screening data set, screening instrument drift was attributed to measurement error, which was addressed by simulation as explained in Appendix D-1.

iii. Mass Emissions Sampling

Mass emissions sampling at the five refineries differed in various ways that may account for some of the differences in results.

Sampling Rates

The sampling rates for samples taken at Refinery A were approximately one-third the rate for samples taken at the other four refineries (~ 0.30 liter/minute versus ~1.0 liter/minute). The corresponding sample run time for samples at Refinery A was approximately three times longer than samples taken at the other refineries. The difference in sampling run times meant that a given volume of sample had different retention times within the sorbent media and that the potential sample variation due to potential process changes also differed.

Sampling Media

Other than the cannister samples, all samples were taken with coconut charcoal sorbent tube media while components at Refinery A were also sampled with a XAD resin tube. Per the sorbent manufacturer (SKC), XAD tubes are used to adsorb soluble organic compounds while charcoal sorbent tubes are used for primarily non-polar compounds. The reduction in the number of sorbent tubes (from three to two) increased the likelihood of breakthrough which was indicated by the third-party laboratory as likely occurring with sample C004.

Background Influence

There were 39 samples where holes in tent enclosures were made by sampling personnel to “vent bag”. If ambient air was drawn into the enclosure, it may have introduced a bias to the sample. However, in addition to a component sample, background samples were also taken, and background sample measurements subtracted from component sample measurements. Therefore, a potential bias should have been mitigated. However, if rather than pulling in ambient air, sample air was exhausted out of the tent enclosure, it may have impacted sample results if the sample air were not homogenous but rather stratified.

As shown in the Appendix B-3 plots of sample results by refinery and sample number, the background concentrations of hydrocarbons varied by refinery. Refinery A had the most background samples with results measured above the detection limit as well as the greatest background measurements in magnitude. Background sample A023 had results that dwarfed those of the component sample with peaks centered around C_{13} as Tridecane and a C_{13} peak concentration of 188,818 µg/m^3.

However, most background concentrations measured during screening were below 10 ppmv with the highest background concentration measured to be 29 ppmv as shown in Table B-1-2 of Appendix B-1.

Sampling Limitations

There were several limitations that prevented sampling of all selected components including accessibility, change in leak magnitude, and component external temperature.

Some components that were initially selected for sampling were found to be inaccessible at the time of sampling, most often due to scaffolding that was erected in between screening and sampling.

Other components were not sampled because either the leak location could not be identified, or the magnitude of the leak changed such that it fell out of the screening value range that was the basis for selecting the component for sampling.

Neither of the above reasons is likely to influence Study results as there was not an apparent connection between the components other than the reason for not sampling.

However, there was a temperature limitation where components with external temperatures above a certain temperature (approximately 400 degrees Fahrenheit) were not sampled and this may have impacted Study results.

As shown in Section III.iv.1 Regression Analysis and in Appendix D-1, mass emissions were found to correlate with temperature. If higher temperature components could have been sampled, the regression analysis and resulting emissions estimated may differ from current estimates.

Sample Shipment Periods

There were varying time periods between when a sample was taken and when it was sent to the third-party laboratory. Some samples were sent the same day as sampling while others were shipped up to 15 days in after sampling. In general, there is an increased risk of sample contamination or sample volatilization (loss of sample) the more time that elapses between when a sample is taken and when it is analyzed.

Field Spike Recoveries

Field spike recoveries – where known amounts of different analytes were introduced into the sampling train and then the amount recovered in the laboratory compared to the amount introduced – widely varied by petroleum refinery and by compound (see Table III-84). The largest differences in recoveries occurred in the initial samples at Refinery A and attenuated by the field spike recovery samples at Refinery E. This may be attributed to sampling technique as the same sampling personnel were used at all five petroleum refineries.

However, there were certain compounds where field recoveries were especially poor or too great at all five petroleum refineries: C_9 to C_{15} compounds.

Replicate Sampling

With every component sample, a primary and replicate sample was taken. Replicate samples taken at Refinery A and some at Refinery B were taken sequentially after the primary sample while replicate samples taken at the other petroleum refineries were taken in parallel with the primary sample. The greatest difference between primary and replicate samples was shown to be where replicate samples were taken sequentially (Figure III.79 and Figure III.80) where operational differences occurring between the time a primary sample and replicate sample were taken could not be discounted as the cause for the difference.

Repeated Sampling

As demonstrated in Figure III.81, measured emissions from a component tended to increase with sequential sampling. This may be because sampling technique improved with familiarity of the component by sampling personnel, because of a change in process conditions, or a physical impact of bagging on the component and the leak.

Sampling technique would be expected to improve with repeated sampling of a component as sampling personnel would have a greater understanding of where to affix and position sampling materials.

Changing process conditions could explain the trend as 11 components is a small statistical sample size to discount random variation.

Another possibility is that the process of sampling a component (affixing a tent enclosure, pulling a vacuum, sampling, etc.) impacts a component leak. This may be likely if there were accumulated, solidified material on the component around the location of the leak. However, such material does not appear to be present when viewing the bagging photographs (Appendix E) of the components that were repeatedly sampled.

Lighter Compounds

All samples were analyzed for C_5 to C_{24} compounds while any collected condensate was analyzed for C_5 to C_{30} compounds. These compounds were selected as they were likely to be present in stream materials designed as heavy liquid (having an initial boiling point greater than 302 degrees Fahrenheit). Lighter compounds (C_1 to C_5) were not expected to be present in significant amounts in heavy liquid streams and therefore, samples were not required to be analyzed for these compounds to reduce sampling and laboratory costs.

However, to verify whether this assumption was correct, the Air District sampled four components handling different stream materials (recycled gas oil, light gas oil / heavy gas oil, diesel, and fractionator bottoms) in two different process units (fluidized catalytic cracking unit, hydrotreater) at Refinery A. Samples were analyzed for C_1 to C_{30} compounds.

If the total mass of the C_1 to C_4 compounds exceeded five percent of the total mass of all 30 analyzed compounds from each component, then these results would either be applied to the other samples by use of a scaling factor or samples would need to include the C_1 to C_4 compounds.

As shown in Table III-44 and Figure III.36 to Figure III.43, total emissions of C_1 to C_4 compounds were a fraction of the total emissions from each component (less than one percent). Therefore, it was assumed that the other component leaks that were sampled had negligible amounts of C_1 to C_4 compounds and these results were not included in the average emissions rate analysis.

iv. Laboratory

Laboratory reports that accompanied sample results noted several potential issues that may affect results.

Sampling Media

Multiple sample media were received by the laboratory with cracked or broken tube end caps (Samples B015, D03A2, D04A2, D023A1, D034) or broken tube (A017A1 XAD tube).

Breakthrough

Sample breakthrough was noted as likely occurring with sample C004 where the back half of the second sorbent tube was found to have a significant catch for pentane (~10.7 percent of the total catch).

Sample C004 had the highest measured pre-bag screening value (28,300 ppmv) of all sampled components and had a post-test screening measurement that flamed out the screening instrument, which typically occurs at screening values of 100,000 ppmv or greater.

Measured emissions from sample C004 were the second greatest of all samples and may have been the greatest if an additional sorbent tube were used such as the XAD tube.

Recoveries

Laboratory control sample recoveries varied by petroleum refinery but similar to field spike recoveries, laboratory control sample recoveries for Refinery A differed from the other four refineries with a minimum of 28 percent and a maximum of 191 percent for Refinery A and a minimum of between 64 percent to 78 percent and a maximum between 130 percent to 163 percent for the other petroleum refineries (Table III-85).

v. Analyses

During the analysis of screening and sampling results, multiple considerations and decisions were made that may have impacted Study results.

Component Categorization

The component types of multiple components were revised from what was entered by screening and/or sampling personnel within field data sheets to align with the component type definitions used within this Study.

Entries for pressure relief devices or pressure relief valves that did not relieve to atmosphere were reclassified as connectors. This was determined through visual inspection of digital photographs taken of a component during screening or sampling as well as through discussions with the relevant petroleum refinery.

Entries for pump housing that were initially classified as a pump seal were revised to connectors. In addition, there were multiple samples of pump components but unless the seal(s) was being sampled, these entries were revised to connectors (these were either the pump housing or connectors such as bull plugs off the pump housing).

Prior to the Study, after discussions with sampling personnel, it was determined to classify a valve as both the valve stem and valve bonnet flange. Typically, the valve bonnet flange is considered by the Air District as a connector. However, because it would be difficult to only enclose a valve stem without also enclosing the valve bonnet flange, it was decided that for the purpose of the Study, both the valve stem and valve bonnet flange would be considered a valve. However, if a sample only included a valve bonnet flange and did not include the valve stem, this sample was considered a connector as the valve stem is considered the defining feature of a valve and the location where leaks most often occur.

Leak Detection and Repair

The purpose of a leak detection and repair program is to routinely look for leaks and repair any found leaks. As such, both component leak frequency and component leak magnitude are expected to decrease when enrolled within an inspection program. This has been demonstrated in previous EPA studies.

There were 97 screened components that were identified as being in heavy liquid service but included within a leak detection and repair program. Three components were at Refinery B while the remainder were at Refinery A. Of the 97, three were pump seals, 41 were connectors, and 53 were valves. The highest screening value measured for pump seals was 65 ppmv. However, there were two connector screening values of over 1,000 ppmv (1797 ppmv and 5024 ppmv). For valves, the highest screening value measured was 500 ppmv.

To determine whether including these components would bias results low (as would be expected), an analysis was done including and excluding these components.

As shown in Table III-73, including these components did not impact average emissions for pump seals, which was anticipated from the low number of such pump seal components and the low magnitude of measured screening values.

However, including the valves and connectors increased the average emission rates for valves by 12 percent and for connectors by one percent. Because these components were monitored within a leak detection and repair program, it is hypothesized that emissions from these components would have been higher had they not been routinely monitored.

Steam Quenched Pump Seals

Steam quenched pumps use pressurized steam quenching to prevent solid material from forming (e.g., coke formation) on the seal as well as either heat or cool a seal depending on the temperature of the material. The steam acts as a barrier fluid for preventing hydrocarbon leaks. However, field personnel encountered examples of steam quenched pumps with steam billowing out of the seals.

At low injection rates, steam acts as barrier for preventing equipment leaks. However, at high injection rates (over pressurization) seal failure can occur and steam may carry initiate leaks. This was found to be the case for one steam quenched pump seal. However, this pump seal leak could not be sampled or even screened near the seal because of the steam, which caused screening instruments to malfunction. Neither the Air District nor petroleum refinery subject matter experts could determine a method to sample this pump seal leak.

Turning off steam quenching has two problems: safety and emissions representativeness.

First, it may be unsafe for a pump to turn off a steam quenching system, even for short durations, as it may cause a rotating shaft to seize, cause coke formation, and/or initiate a fire.

Second, the steam quenching system itself may be the cause of a leak or affecting the magnitude of a leak. The results from turning of a steam quenching system and screening and/or sampling may not be representative of the actual emissions. This is more likely the case where steam prevents screening at or near the pump seal because the steam may be causing and masking a leak. However, if screening could be conducted at the surface without interference from steam, it would not be necessary to turn off the steam quenching.

This Study and previous studies have shown that most fugitive emissions derive from a small percentage of components and that leaks are not normally distributed. If this pump could have been sampled, because it had a screening value of 760 ppm at over a foot or more from the surface and had a steady hydrocarbon stream leaking from the seal, it is conceivable that it the mass emissions from this pump seal would have dominated the average emission rate found for pump seals.

Not all steam quenched pumps had steam billowing out of the seals that prevented screening. Some pumps were able to be screened. Screeners made a best attempt at screening at the pump seal surface and where steam was present screened as close as they could without damaging the screening instrument. However, the distance at which screeners took measurements was not recorded.

Because fugitive leaks are not normally distributed, emissions are skewed, and the inability to sample the steam quenched pump seal found to have the greatest screening value; steam quenched pump seals were treated as a separate category of pump seals and excluded from the average emissions rate analysis.

It is recommended that emissions from such pump seals be evaluated in a future study when such pump seals may be sampled and measured without turning off the steam quenching system.

Non-Process Lube Oil Components

Components handling non-process lube oil (e.g., pump seal pots and lubricating systems) were excluded from the average emissions rate analysis as emissions from these components will be evaluated in a separate study, the Lube Oil Study.

Gaseous Phase Components

While screening at Refinery D, multiple components were found have significant measured screening values including two that had screening values greater than 10,000 ppmv. These components were found to be handling material that had an initial boiling point greater than 302 degrees Fahrenheit but in the gaseous phase. These components were not including the Refinery D's leak detection and monitoring program. It was found that some refineries were including these within their LDAR programs while others were not. In an agreement submitted to the Air District by the five petroleum refineries, they agreed to include all such component within their LDAR programs. As such, these components were excluded from the average emission rate analysis.

Pump Seals / Pump Housing

Entries for pumps varied by refinery. At Refineries B, C, D, and E; separate entries were made for pump seals and pump housing. However, at Refinery A, screening personnel entered one entry for both the pump seal and pump housing and entered the maximum screening value found at either the pump seal or pump housing. Some of these entries had comments from screening personnel as to the location of the maximum leak. Entries that had comments noting pump housing were revised to connectors. Otherwise, they were left as pump seals. Where a comment was made noting the location as a pump seal, this choice was obvious. However, there were 103 entries that included a screen measurement but did not include a comment as to the location of the leak. It was decided that the location of a leak was more probable to be at the pump seal then at the pump housing.

Component Size

As components vary in shape and configuration, it was decided to use the process line diameter to have components compared on the same basis. Component size was used as a surrogate for an approximation of the amount of potential length of component surface where a leak may occur. Using the process line diameter, length was estimated by using the equation for estimating the circumference of a circle. This approximation would be closest for flanges and least accurate for valves with welded bonnet flanges where leaks would occur at the valve stem, in which case the diameter of the valve stem should be used.

Large Leakers

During the Study, there was a concern that because of the Study design (only two process units were initially selected for screening of connectors and valves), the screening portion may not adequately represent the true distribution of leaks and may exclude potentially significant leaks resulting in lower emissions estimates than actual.

The use of a Forward Looking InfraRed (FLIR) optical camera to scan each process unit at each petroleum refinery was explored. However, there were several concerns with this approach:

- the operator skill needed to correctly position the camera at each leak point for a valid reading,
- potential interference or masking of leaks by steam, clouds of which are ubiquitous within each petroleum refinery, and
- the high threshold for identifying leaks, potentially missing moderate to significant leaks.

Believing that the likelihood of such leaks was limited to a few process lines, one petroleum refinery manager offered to use their subject matter experts to identify process lines within their petroleum refinery through knowledge of their operating conditions and physical chemistry calculations. However, this effort was halted when the petroleum refinery personnel determined more process lines than expected would be affected and it became a daunting task.

Ultimately, this effort ceased once several components with leaks were discovered with screening values above 10,000 ppmv were identified.

However, as shown in Appendix D-1, there is a high probability that the Study did not capture large connector or valve leaks (i.e., the distribution of screening values for the screened connectors and valves does not reflect the actual distribution). This may be attributed to the selection process for connectors and valves.

Screening a portion of every process unit with heavy liquids service components at each petroleum refinery through stratified random sampling is likely to result in a distribution that is closer to actual.

Regression Equations

As discussed within Appendix D-1, screening value, operating temperature, and operating pressure were found to be correlated to measured sample emissions. However, because approximately 30 percent of the screened component data set (see Table B-1-1 of Appendix B) was missing entries for operating pressure, operating pressure was not included as an additional variable within developed regression equations.

Temperature

Temperature was found to correlate with measured sample emissions and was used as a variable within derived regression equations. However, because sampling personnel could not sample components with external temperatures above a given threshold, there is a wider range of component temperatures within the screening data set than in the sampling data set. Because of this, the regression equations use a cutoff for temperature (the highest temperature measured for a sampled component). If components with higher temperatures could have been sampled, it is likely that either the regression equations and/or emissions results would be different.

vi. Comparison to Previous Studies

There have been several studies where emissions from components in heavy liquid service have been evaluated. The two studies whose results are in use currently are the 1980 EPA Study and the 1993 EPA Study, whose results were revised and incorporated into CAPCOA's 1999 "Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities".

In the 1980 EPA Study, average emission factors were derived that are currently in use for estimating emissions from components in heavy liquid service that are not monitored within an LDAR program.

In the 1993 EPA Study and subsequent revisions within the 1999 CAPCOA Guidelines, correlation equations were derived for estimating emissions from components that are routinely monitored and repaired within an LDAR program.

IV.vi.1. 1980 EPA Study

There were multiple differences between the 1980 EPA Study and the Heavy Liquids Study in study design, methodology, and analysis which make a comparison between the two studies difficult.

Study Design

The significant differences in study design between the 1980 EPA Study and the Heavy Liquids Study was the number of components that were studied as well as how those components were selected.

Both studies screened components and sampled some portion of the screened components. The difference in the number of screened and sampled components by study is presented in Table IV-1.

Table IV-1. Comparison of Number of Components Screened and Sampled Between 1980 Study and Heavy Liquids Study

Component Type	Number of Components Screened		Number of Components Sampled	
	1980 [1]	Study	1980 [4]	Study
Valves	485	5,349	32	70
Connectors	Unknown [2] (2,094 Maximum Possible)	4,710	Unknown [5] (62 Maximum Possible)	61
Pump Seals	292	734	66	32 [6]
Pressure Relief Valves	0 [3]	30	0 [3]	0
Total	777 (2,871 Maximum Possible)	10,823	98 (160 Maximum Possible)	163

Notes:

1. Source: Table 5-1 of EPA 1980 Volume 1. Only includes components in heavy liquid service.
2. 2094 flanges in all streams (gas, light liquid, and heavy liquid) were noted as being screened. The specific number of flanges in heavy liquid service that were screened is not known.
3. Per the "Pressure Relief Devices" section on Page 61 of 1980 EPA Volume 1, only pressure relief valves in gas service were selected for testing.
4. Source: Table 5-4 of EPA 1980 Volume 1. Only includes components in heavy liquid service.
5. 62 flanges in all streams (gas, light liquid, and heavy liquid) were noted as being sampled. The specific number of flanges in heavy liquid service that were sampled is not known.
6. Includes one sample of an agitator seal

Comparison of Screening Results

The 1980 EPA Study did not provide screening results for connectors (flanges only) in different stream services so the screening results for only valves and pump seals are provided in the following table.

Table IV-2. Comparison of Number Components within Different Screening Ranges Between 1980 Study and Current Study

Component Type [1]	Screening Range [2] (ppmv)	Number of Components within Screening Measurements within Listed Range			
		1980 [3]		Study	
		Number	Percent	Number	Percent
Valves	0	335	69.1	365	6.8
	1 - 200	121	25.0	4,902	91.6
	201 – 1,000	21	4.3	48	0.9
	1,000 – 10,000	7	1.4	31	0.6
	> 10,000	1	0.2	3	0.1
	All	**485**	**100**	**5,349**	**100**
Pump Seals	0	114	39.0	26	3.5
	1 - 200	115	39.4	690	94.0
	201 – 1,000	24	8.2	14	1.9
	1,000 – 10,000	28	9.6	3	0.4
	> 10,000	11	3.8	1	0.1
	All	**292**	**100**	**734**	**100**

Notes:
1. The 1980 Study only listed flanges in all streams (did not provide for only heavy liquid service)
2. For comparison's purposes, the screening ranges are those that were listed within the 1980 Study.
3. Source: Table 5-3 of EPA 1980 Volume 1

The results listed in Table IV-2 do not account for differences in screening instruments between the 1980 EPA Study and the Heavy Liquids Study. In the 1980 EPA Study, a Bacharach Threshold Limit Value (TLV) Sniffer was used to screen instruments. The TLV Sniffer is a type of catalytic combustion analyzer, which differs in operating principle from a flame ionization detector, used in the Heavy Liquids Study.

The specific model instrument used in the Heavy Liquids Study was the Thermo Fisher Scientific TVA 2020 model instrument.

As discussed in Section I.iii.5 (**API Publication Number 332**), the Western States Petroleum Association and the American Petroleum Association carried out a study to understand differences in measured screening values by four different screening instruments including the Bacharach TLV Sniffer and a Thermo Fisher Scientific Foxboro TVA 1000. The TVA 1000 was an earlier model instrument than the TVA 2020. The study found measured screening values varied by instrument and derived equations (see Table I-15) for converting screening values between the four different instruments.

Using these equations, the screening values measured during the Heavy Liquids Study may be converted so that they are on the same basis as those in the 1980 EPA Study. Additionally, the 1980 EPA Study reported maximum screening values that were not corrected for background. The following table provides the results of both adjustments.

Table IV-3. Comparison of Screening Results of the 1980 Study and Current Study on the Same Basis

Component Type [1]	Screening Range [2] (ppmv)	Number of Components within Screening Measurements within Listed Range			
		1980 [3]		Study	
		Number	Percent	Number	Percent
Valves	0	335	69.1	689	12.9
	1 - 200	121	25.0	4,601	86.0
	201 – 1,000	21	4.3	8	0.8
	1,000 – 10,000	7	1.4	1	0.3
	> 10,000	1	0.2	0	0.0
	All	485	100	5,349	100
Pump Seals	0	114	39.0	43	5.9
	1 - 200	115	39.4	682	92.9
	201 – 1,000	24	8.2	7 [4]	1.0
	1,000 – 10,000	28	9.6	1	0.1
	> 10,000	11	3.8	1 [4]	0.1
	All	292	100	734	100

Notes:

1. The 1980 Study only listed flanges in all streams (did not provide for only heavy liquid service)
2. For comparison's purposes, the screening ranges are those that were listed within the 1980 Study.
3. Source: Table 5-3 of EPA 1980 Volume 1
4. Component A-477 was measuring 760 ppmv at over a foot distance from the seal and had a steady stream of hydrocarbons leaking and forming a pool at the base of the pump.

Comparison of Regression Equations

Both studies developed regression equations to estimate emissions from screened components that were not sampled.

The 1980 EPA Study proposed a linear equation of the following form:

$$\log_{10} L = B_o + B_1 \log_{10} M \qquad [III\text{-}2]$$

where:

L = nonmethane hydrocarbon leak rate (lb/hour)

B_o, B_1 = constants, regression intercept and regression coefficient (slope), respectively

M = maximum screening value (ppmv)

The Study proposed a similar linear equation with an additional term:

$$\log_{10} L = B_o + B_1 \log_{10} M + B_2 T \qquad [III\text{-}3]$$

where:

L = nonmethane hydrocarbon leak rate (kg/hour)

B_o, = constant, intercept

B_1, B_2 = constants, regression coefficients

M = maximum screening value (ppmv)

T = component temperature (degrees Fahrenheit)

Along with the additional variable, the regression equations have different screening values as the input.

The 1980 EPA Study utilized the maximum screening value recorded for a component without adjustment for ambient background concentrations.

The regression equations derived for the Heavy Liquids Study use the net screening value where the screening value of the ambient atmosphere within several feet of the component is subtracted from a component's maximum screening value.

Further, as discussed previously, a different model screening instrument (TLV Sniffer) was used in the 1980 EPA Study than the Heavy Liquids Study (TVA 2020) and a previous WSPA study identified differences in screening values by different screening instruments.

Repeated (duplicate) measurements were taken at each of the five petroleum refineries. However, the Air District only measured emissions at two of the five petroleum refineries whereas Tricord measured emissions at all five petroleum refineries and comprised the majority (over 90 percent) of the total bagged measurements available for analysis. Although measures were implemented to minimize potential differences between bagging conducted by the Air District and Tricord, there may still be differences in the measurements due to personnel, equipment, and bagging techniques.

To understand these differences, bagged data was analyzed under eight scenarios depending on:

- the component leak concentration measured right before bagging,
- whether the measurement is an initial or duplicate measurement of a component, and
- the party that conducted the bagging.

Scenario	Description	Screening Values
1	All measurements, including duplicates	0 ≤ ppmv < 10,000
2	No duplicate measurements, use first chronological bagged measurement	0 ≤ ppmv < 10,000
3	No duplicate measurements, use first Tricord measurement of any duplicates	0 ≤ ppmv < 10,000
4	No duplicate measurements, use first Tricord measurement of any duplicates, no Air District measurements	0 ≤ ppmv < 10,000
5	All measurements, including duplicates	10 < ppmv < 10,000
6	No duplicate measurements, use first chronological bagged measurement	10 < ppmv < 10,000
7	No duplicate measurements, use first Tricord measurement of any duplicates	10 < ppmv < 10,000
8	No duplicate measurements, use first Tricord measurement of any duplicates, no Air District measurements	10 < ppmv < 10,000

With these caveats, the regression parameters by component type between two studies are listed in the following tables. Regression parameters for eight different regression scenarios are shown to provide an indication of the variability depending upon which bagged samples are included in the regression analysis for the Heavy Liquids Study.

Table IV-4. Regression Parameters for Valves and Connectors for the 1980 Study and Heavy Liquids Study

Scenario	Regression Coefficients			Regression Standard Errors			Adjusted R^2	Data Pairs (N)
	Intercept	Screening Value	Temperature	Intercept	Screening Value	Temperature		
1980 Study (1) (Valves) (2)	-9.82	2.26	N/A	1.12	0.34	N/A	0.96 (3)	4
1	-7.415	1.088	0.00261	0.117	0.044	0.00027	0.842	141
2	-7.454	1.116	0.00255	0.120	0.047	0.00029	0.846	130
3	-7.472	1.122	0.00263	0.117	0.045	0.00029	0.857	128
4	-7.498	1.128	0.00273	0.117	0.046	0.00030	0.861	126

Notes:
1. Source: Table 5-7 of EPA 1980 Volume 1
2. This is the R^2 and not the adjusted R^2 value, which was not provided in the 1980 Study

The 1980 EPA Study did not derive a separate regression equation for connectors (flanges) in heavy liquid service. Regression equations for valves and pump seals were derived but were derived with less data pairs (four for valves, 17 for pump seals) than were used in the Heavy Liquids Study.

As shown in Appendix D-1, the differences among the scenario fits were found to be indistinguishable statistically.

Screening instruments were seen to experience the largest average drift with the 10 ppmv calibration gas (see Tables C-2-1 through C-2-5 of Appendix C-2). Thus, screening measurements less than 10 ppmv were determined to not be as accurate as larger measurements.

Differences were found between measurements conducted by the Air District and by TRICORD for the same component. However, the Air District and TRICORD only sampled three of the same components, which was an insufficient number to determine whether the differences in measurements was the result of a bias within the sampling or attributed to differences in the process at the time of sampling.

As such, measurements of one or another sampling team could not be excluded, or bias adjusted.

In addition, to mitigate the potential impact that bagging may have on a leak, it was decided that the first sample should be used when multiple samples were taken of the same component, except where the first sample had a known issue (e.g., broken sample tube), in which case, the first valid sample was used.

Therefore, Scenario 6 (no duplicate measurements, use of first sample taken where a component was sampled multiple times) was used in determining average emission factors.

Comparison of Average Emission Factors

A comparison of study results by component type is provided in **Table IV-6**.

Table IV-6. Average Emissions Rates and Confidence Intervals by Component Type and Study

Component Type	1980 EPA Study [1]		Heavy Liquids Study	
	Emission Factor (kg/hour/component)	95% Confidence Interval (kg/hour/component)	Emission Factor (kg/hour/component)	90% Confidence Interval (kg/hour/component)
Connectors [2]	2.54E-04	(9.07E-05, 1.13E-03)	9.4E-06	(6.6E-06, 1.60E-05)
Valves	2.27E-04	(9.07E-05, 6.80E-04)	2.84E-05	(1.80E-05, 4.43E-05)
Pump Seals	2.09E-02	(8.62E-03, 4.99E-02)	1.18E-04	(4.82E-05, 4.87E-04)

Notes:

1. Source: Table 5-6 of EPA 1980 Volume 1 (converted to metric units)
2. The 1980 EPA Study listed values for flanges handling all process streams (gas, light liquid, and heavy liquid)

As shown in the table, results from the Heavy Liquids Study were both lower than those found in the 1980 EPA Study as well as had as had narrower confidence intervals than resulted from the 1980 EPA Study. This is easier shown when plotted in **Figure IV.1** and in **Figure IV.2**.

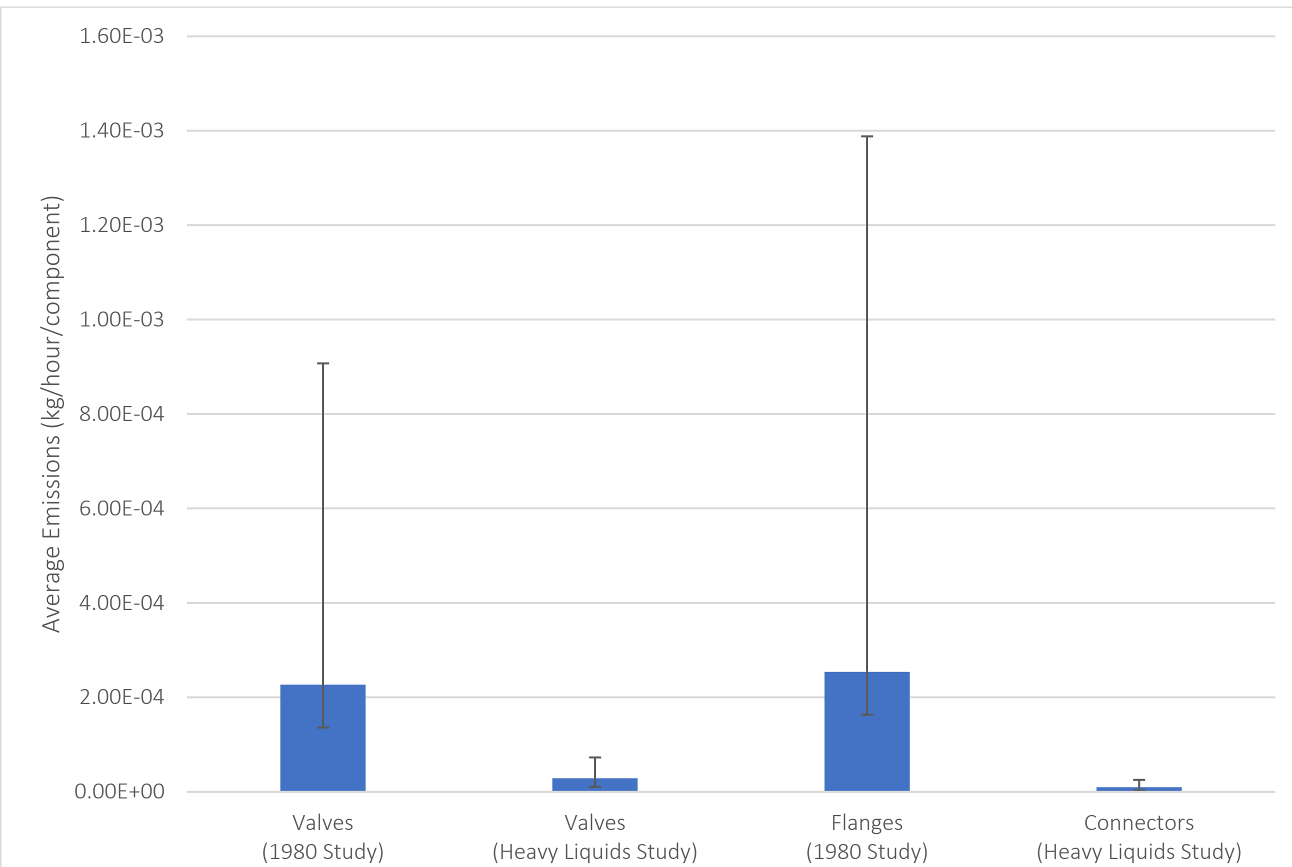

Figure IV.1. Plots of 1980 Study and Study Average Emission Rates and Confidence Interval for Valves and Connectors

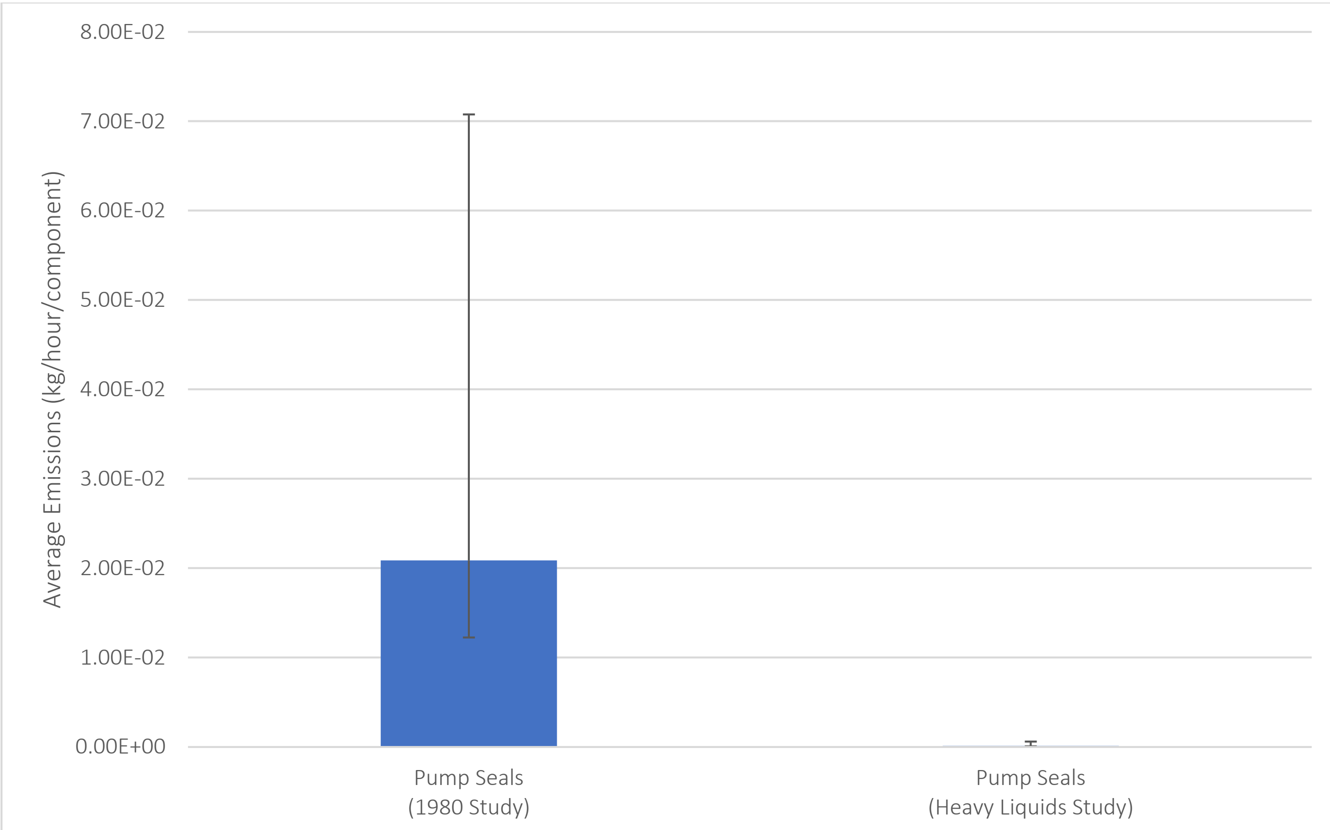

Figure IV.2. Plots of 1980 Study and Study Average Emission Rates and Confidence Interval for Pump Seals

As shown in **Table IV-6**, **Figure IV.1**, and **Figure IV.2**; average emission rates for valves, connectors, and pump seals from the Heavy Liquids Study were found to be much lower than those found in the 1980 EPA Study.

The 1980 EPA Study listed an average emission rate for flanges rather than all connector types and grouped flanges of all service types (gas, light liquid, and heavy liquid) together. This would be expected to produce a higher average emission rate than if including all connector types and only those in heavy liquid service.

As discussed previously, there is a greater probability of missing large leakers, which may increase average emission rates for both valves and connectors.

A comparison of results between the 1980 Study and the Heavy Liquids Study is difficult because of the number of methodological differences.

The following table identifies some of the significant methodological differences between the 1980 EPA Study and the Heavy Liquids Study.

Table IV-7. Some of the Methodological Differences Between the 1980 EPA Study and the Heavy Liquids Study

Phase	Item	1980 EPA Study	Current Study
Study Design	Process Units / Components	In each refinery: 6 to 9 process units	Pump Seals: All targeted Pressure Relief Valves: All targeted Connectors: Only two process units* Valves: Only two process units* * Expanded as necessary
	Component Selection	Individual components selected from piping and instrumentation diagrams prior to screening	Process lines selected by facility drawings prior to screening
Screening	Instrument	Bacharach TLV Sniffer (Catalytic combustion analyzer)	Thermo Fisher Scientific TVA-2020 (Flame ionization detector)
	Calibration	Two-Point (500 – 525, 2000 ppmv)	Six-Point (Zero, 10, 100, 500, 3,000, 10,000 ppmv)
	Personnel	EPA Contractor Personnel	Refinery A: Air District Personnel Refinery B (partial): Air District Personnel Refineries B, C, D, and E: Refinery Personnel
Sampling	Bagging	Total Hydrocarbons: Vacuum Method Species: Blow-Through Method	Total Hydrocarbon: Vacuum Method Species: Vacuum Method
Laboratory	Laboratory	Mobile Laboratory (Located Onsite)	Third-Party (Located in North Caroline)
	Quantitative Analysis	Gas Chromatograph resolved hydrocarbon mixtures into two peaks (methane, non-methane)	Gas Chromatograph resolved hydrocarbon mixtures into 20 peaks (C_5 to C_{24}) for all samples and 26 peaks (C_5 to C_{30}) for condensate samples

Any differences in the results of the Heavy Liquids Study and the 1980 EPA Study cannot be differentiated from methodological reasons, equipment technology (e.g., valve stem packing or gasket materials), or refinery maintenance, inspection, and repair practices (either regulatory driven or corporate policy).

Identifying the specific reason(s) for differences in results was deemed outside the scope of the Study.

IV.vi.2. 1993 Refinery Study / 1999 CAPCOA Guidelines

The 1993 Refinery Study and 1999 CAPCOA Guidelines did not produce average emission factors for non-monitored components in heavy liquid service. Rather, they incorporated the average emission factors from the 1980 EPA Study.

Further, because the intent of the 1993 Refinery Study was to derive new correlation equations rather than average emissions, a random sampling of components was not done. Rather, components within given screening ranges were located and then sampled. Therefore, the 1993 Refinery Study screening results would not be a representative sample as a comparison to those found in the Heavy Liquids Study.

IV.vi.3. WSPA Study / API Publication Number 337

Although the 1996 API Study published proposed average emission factors for components in heavy liquid service, it did not include sampling of components for mass emissions but rather used screening results with correlation equations derived in another study, the 1993 Refinery Study.

The 1996 API Study compiled screening data from four Southern California petroleum refineries and conducted screening at two Washington state petroleum refineries. The results of both efforts are shown in Table I-18 and Table I-19.

As discussed previously, a separate WSPA / API study (see Section I.iii.5 **API Publication Number 332**) determined that measured screening results vary by the specific model screening instrument used.

However, API Publication Number 337 only listed the specific model screening instrument used (Foxboro OVA 108) for one of the California petroleum refineries. Therefore, a comparison of screening results on the same basis as was done with the 1980 EPA Study could not be done.

vii. Potential for Re-Evaluating Average Emission Factor

The results of this Study are dependent upon the categories of components that were Studied. Average emission factors (kg/hour/component) derived in this Study represent emissions from those components that were studied.

The intent of this Study was to evaluate emissions from components in heavy liquid service that are not routinely monitored for leaks and repaired as such components would be expected to have lower emissions than non-monitored components.

Emissions from components that are routinely monitored and repaired are currently estimated using monitoring results and a set of correlation equations outlined in CAPCOA's 1999 "Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities".

If in the future, certain categories of components that are currently not routinely monitored and repaired are required to be routinely monitored for leaks and any found leaks required to be repaired, it may be necessary to re-evaluate the average emission factors.

Since emissions from these components were included in the data set used to derive the average emission factors, emissions from such components may be double counted as they would be included in the average emission factors used to estimate emissions from non-monitored components as well as reported in the emissions estimates of monitored components.

To prevent this, emissions from such components would need to be removed from the data set used to derive the average emission factors and the average emission factors would need to be re-derived.

However, average emission factors represent the average emissions from such components across all five petroleum refineries and not necessarily the emissions of a single component. Emissions from a given component may be higher or lower than the average emission factor but not in the aggregate.

Therefore, unless all components in given category of components were routinely monitored and repaired at all such facilities, revising the average emission factors would not be applicable.

viii. Future Studies

There were multiple lessons learned from this Study where either something was not considered prior to the Study but would have strengthened results or improvements could be made in the steps and approaches taken.

There were also additional areas and categories of components identified that may warrant future evaluation.

Suggested improvements in study design:

- sample a minimum number and diversity (component types) of components at every process unit within each petroleum refinery under study,
- consider using a stratified random sampling technique,
- categorize and number components by category of interest (process unit, process stream, operating temperature, operating pressure, size, etc.) on petroleum refineries and randomly select individual components for inclusion.

Suggested improvements in screening technique and information collection:

- use a standard tool to measure screening distance (if not at interference) as well as to measure at 1 centimeter from the interface,
- pre-establish objective metrics for different vibration amounts (none, low, medium, high),
- use of portable vibration monitor,
- use of electronic means for recording screening values (like handhelds used in LDAR programs),
- record the number of pump seals by pump and pump subtype,
- use heated equipment to prevent potential condensation within the screening instrument,
- determine instrument response times to various materials at different temperatures before study and provide to screening personnel for use in screening, and
- for each selected process line (where stream materials and operating temperatures are the same), determine response time to a known leak and use that time for all measurements of that process line.

Suggested improvements in sampling technique and information collection:

- use bagging materials that can withstand temperatures greater than the maximum temperature of study components (in the current Study, 1,000 degrees Fahrenheit).

Potential categories of components or areas for further emissions study:

- emissions from components handling non-process oil (Lube Oil Study),
- emissions from pumps with steam-injection seals,
- emissions from components other than connectors, pump seals, valves, or pressure relief devices,
- components in proximity to LDAR monitored components, and
- material, age, or type of gasket, packing, or sealing materials used in components.

V. Conclusions

The following conclusions may be made from the Heavy Liquids Study:

Results:

- Average emission rates at the five petroleum refineries for valves, connectors, and pump seals in heavy liquid service were lower than previously relied upon assumptions.
- Average emission rates were derived for valves, connectors, and pump seals in heavy liquid service as presented in the following table:

Component Type	Emission Factor (kg/hour/component)	90% Confidence Interval (kg/hour/component)
Connectors	9.40E-06	(6.60E-06, 1.60E-05)
Valves	2.84E-05	(1.80E-05, 4.43E-05)
Pump Seals	1.18E-04	(4.82E-05, 4.87E-04)

- Lighter compounds (C_1 to C_4) were found to comprise only a small portion (less than one percent) of measured emissions although the sample size was limited (emissions from only four components in two process units at one refinery were evaluated).
- Screening values, operating temperature, and operating pressure were found to correlate with measured emissions. However, because of the number of missing operating pressure information for screened components, regression equations were developed using only screening value and temperature.
- Significant differences were found in the responses of screening instruments when screening components in heavy liquid service by process stream material and process stream temperature. Heavier streams typically required longer screening and recovery times for the same component type, subtype, and size.

Issues Uncovered:

- Study design may have impacted results (there is a greater probability of missing large leakers).
- Screening of heavy liquid streams causes screening instruments to drift low (measured screening values are lower than actual).
- Screening pace was faster at Refineries B, C, D, and E, which may have impacted measured screening values (and resulting estimated emissions).
- Study results are dependent upon the petroleum refineries including all components that handle material with an initial boiling point greater than 302 degrees Fahrenheit in the gaseous phase within their leak detection and repair programs.

Recommendations:

- Several improvements (see Section IV. viii. **Future Studies**) were identified for future studies including in study design, screening, and sampling techniques.

- Results include emissions from components in heavy liquid service that are currently not in Air District emissions inventories including:
    - components associated with storage tanks and blending areas,
    - components in process units that do not have components in gas or light liquid service, and
    - components in process units that are not currently covered by the existing estimation methodology.

  Because there is no current methodology for estimating the number of such components, methodologies for estimating these components will need to be developed.
- There were several component types for which average emission rates could not be derived either because there were insufficient numbers, their emissions could not be evaluated, or they are recommended for inclusion in a future study:
    - pressure relief valves that relieve to atmosphere (insufficient numbers),
    - pump seals with steam or hot oil quenching systems (emissions could not be measured),
    - components handling non-process lube oil (included in a future study).

VI. Contributions

The following individuals contributed to the Study without whom, the Study could not have been completed.

Bay Area Air Quality Management District		
Name	Title*	Contribution
Compliance and Enforcement Division		
Chris Crowley	Air Quality Inspector	Pilot Refinery Field Screener
Bert Dare	Air Quality Instrument Specialist (retired)	Screening Instrumentation
Linda Duca	Senior Air Quality Inspector	Field Screening Lead
Edward Giacometti	Manager of Compliance & Enforcement	Study Design – Screening Portion
Jeff Gove	Director of Compliance & Enforcement	Study Design – Screening Portion
Paul Grazzini	Air Quality Specialist	Screening Instrument Calibrations Oversight of Third-Party Auditors
Wayne Kino	Deputy Air Pollution Control Officer	Study Design – Screening Portion
Quentin Malloy	Air Quality Inspector	Pilot Refinery Field Screener
Ron Pilkington	Supervising Air Quality Inspector	Supervised Field Screening
Raymond Salalila	Air Quality Inspector	Pilot Refinery Field Screener
John Swanson	Senior Air Quality Inspector	Pilot Refinery Field Screener
Almira Van	Air Quality Inspector	Pilot Refinery Field Screener
Michael Wedl	Temporary Air Quality Inspector	Auditor – Observing Screening by Refinery Personnel
Simon Winer	Senior Air Quality Inspector	Pilot Refinery Field Screener
Ying Yu	Air Quality Inspector	Pilot Refinery Field Screener
Engineering Division		
Damian Breen	Deputy Air Pollution Control Officer	Direction, Oversight
Pamela Leong	Director of Engineering	Direction, Study Design
Jim Karas	Director of Engineering (retired)	Direction
Greg Stone	Supervising Air Quality Engineer (retired)	Protocol Review
Jaime Williams	Director of Engineering (left Air District)	Protocol Review
Meteorology and Measurement Division		
Jeffrey Aaseth	Air Quality Instrument Specialist	Pilot Refinery Field Sampler
Robert Bartley	Manager (retired)	Sampling Protocol Development
Jerry Bovee	Manager	Study Design – Sampling Portion
George Bradbury	Air Quality Instrument Specialist	Equipment Setup Pilot Refinery Field Sampler
Hiroshi Doi	Supervising Air Quality Instrument Specialist	Equipment Procurement

Bay Area Air Quality Management District		
Marco Hernandez	Principal Air Quality Engineer	Pilot Refinery Field Sampler Laboratory – QC Review
Elaine Ko	Supervising Air Quality Engineer	Study Design – Sampling Portion Sampling Oversight and Review Laboratory Oversight and Review
Charles McClure	Supervising Air Quality Engineer (retired)	Study Design – Sampling Portion
Pon Phithaksounthone	Senior Air Quality Engineer	Sampling / Laboratory – QA/QC Review Contractor Field Testing Oversight
Waiman Pon	Air Quality Instrument Specialist	Screening Instrument Calibrations Sampling / Laboratory – QA/QC Review
Eric Stevenson	Director (retired)	Study Design – Sampling Portion
Michael Wiley	Air Quality Instrument Specialist	Pilot Refinery Field Sampler
Planning Division		
David Fairley	Statistician (retired)	Study Design Statistical Analyses
Legal Division		
Adan Schwartz	Senior Assistant Counsel	Legal Guidance
Administrative Resources		
Cynthia Zhang	Purchasing Agent	Third-Party Auditors Contract Lead
Human Resources		
Judy Yu	Manager	Third-Party Auditor Contracting General Assistance
*The title column includes the title(s) of personnel at time of contribution to the Study.		

In addition to the individuals listed in the table above, there were numerous personnel at the following organizations that contributed their time and expertise to this Study:

- Chevron Richmond Refinery,
- Phillips 66 San Francisco Refinery,
- Shell Martinez Refinery,
- Tesoro Golden Eagle Refinery,
- Valero Benicia Refinery,
- Western States Petroleum Association,
- Tamura Environmental,
- Tricord Consulting,
- Enthalpy Analytical, and
- Bureau Veritas.

APPENDIX A
Methodology

APPENDIX A-1
Screening Methodology

EPA Method 21

While we have taken steps to ensure the accuracy of this Internet version of the document, it is not the official version. Please refer to the official version in the FR publication, which appears on the Government Printing Office's eCFR website:
(http://www.ecfr.gov/cgi-bin/text-idx?c=ecfr&tpl=/ecfrbrowse/Title40/40cfr60_main_02.tpl)

Method 21 - Determination of Volatile Organic Compound Leaks

1.0 Scope and Application

1.1 Analytes.

Analyte	CAS No.
Volatile Organic Compounds (VOC)	No CAS number assigned.

1.2 Scope. This method is applicable for the determination of VOC leaks from process equipment. These sources include, but are not limited to, valves, flanges and other connections, pumps and compressors, pressure relief devices, process drains, open-ended valves, pump and compressor seal system degassing vents, accumulator vessel vents, agitator seals, and access door seals.

1.3 Data Quality Objectives. Adherence to the requirements of this method will enhance the quality of the data obtained from air pollutant sampling methods.

2.0 Summary of Method

2.1 A portable instrument is used to detect VOC leaks from individual sources. The instrument detector type is not specified, but it must meet the specifications and performance criteria contained in Section 6.0. A leak definition concentration based on a reference compound is specified in each applicable regulation. This method is intended to locate and classify leaks only, and is not to be used as a direct measure of mass emission rate from individual sources.

3.0 Definitions

3.1 *Calibration gas* means the VOC compound used to adjust the instrument meter reading to a known value. The calibration gas is usually the reference compound at a known concentration approximately equal to the leak definition concentration.

3.2 *Calibration precision* means the degree of agreement between measurements of the same known value, expressed as the relative percentage of the average difference between the meter readings and the known concentration to the known concentration.

3.3 *Leak definition concentration* means the local VOC concentration at the surface of a leak source that indicates that a VOC emission (leak) is present. The leak definition is an instrument meter reading based on a reference compound.

3.4 *No detectable emission* means a local VOC concentration at the surface of a leak source, adjusted for local VOC ambient concentration, that is less than 2.5 percent of the specified leak definition concentration. that indicates that a VOC emission (leak) is not present.

3.5 *Reference compound* means the VOC species selected as the instrument calibration basis for specification of the leak definition concentration. (For example, if a leak definition concentration is 10,000 ppm as methane, then any source emission that results in a local concentration that yields a meter reading of 10,000 on an instrument meter calibrated with methane would be classified as a leak. In this example, the leak definition concentration is 10,000 ppm and the reference compound is methane.)

3.6 *Response factor* means the ratio of the known concentration of a VOC compound to the observed meter reading when measured using an instrument calibrated with the reference compound specified in the applicable regulation.

3.7 *Response time* means the time interval from a step change in VOC concentration at the input of the sampling system to the time at which 90 percent of the corresponding final value is reached as displayed on the instrument readout meter.

4.0 Interferences[Reserved]

5.0 Safety

5.1 Disclaimer. This method may involve hazardous materials, operations, and equipment. This test method may not address all of the safety problems associated with its use. It is the responsibility of the user of this test method to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to performing this test method.

5.2 Hazardous Pollutants. Several of the compounds, leaks of which may be determined by this method, may be irritating or corrosive to tissues (*e.g.*, heptane) or may be toxic (*e.g.*, benzene, methyl alcohol). Nearly all are fire hazards. Compounds in emissions should be determined through familiarity with the source. Appropriate precautions can be found in reference documents, such as reference No. 4 in Section 16.0.

6.0 Equipment and Supplies

A VOC monitoring instrument meeting the following specifications is required:

6.1 The VOC instrument detector shall respond to the compounds being processed. Detector types that may meet this requirement include, but are not limited to, catalytic oxidation, flame ionization, infrared absorption, and photoionization.

6.2 The instrument shall be capable of measuring the leak definition concentration specified in the regulation.

6.3 The scale of the instrument meter shall be readable to ±2.5 percent of the specified leak definition concentration.

6.4 The instrument shall be equipped with an electrically driven pump to ensure that a sample is provided to the detector at a constant flow rate. The nominal sample flow rate, as measured at the sample probe tip, shall be 0.10 to 3.0 l/min (0.004 to 0.1 ft^3 /min) when the probe is fitted with a glass wool plug or filter that may be used to prevent plugging of the instrument.

6.5 The instrument shall be equipped with a probe or probe extension or sampling not to exceed 6.4 mm (1/4in) in outside diameter, with a single end opening for admission of sample.

6.6 The instrument shall be intrinsically safe for operation in explosive atmospheres as defined by the National Electrical Code by the National Fire Prevention Association or other applicable regulatory code for operation in any explosive atmospheres that may be encountered in its use. The instrument shall, at a minimum, be intrinsically safe for Class 1, Division 1 conditions, and/or Class 2, Division 1 conditions, as appropriate, as defined by the example code. The instrument shall not be operated with any safety device, such as an exhaust flame arrestor, removed.

7.0 Reagents and Standards

7.1 Two gas mixtures are required for instrument calibration and performance evaluation:

7.1.1 Zero Gas. Air, less than 10 parts per million by volume (ppmv) VOC.

7.1.2 Calibration Gas. For each organic species that is to be measured during individual source surveys, obtain or prepare a known standard in air at a concentration approximately equal to the applicable leak definition specified in the regulation.

7.2 Cylinder Gases. If cylinder calibration gas mixtures are used, they must be analyzed and certified by the manufacturer to be within 2 percent accuracy, and a shelf life must be specified. Cylinder standards must be either reanalyzed or replaced at the end of the specified shelf life.

7.3 Prepared Gases. Calibration gases may be prepared by the user according to any accepted gaseous preparation procedure that will yield a mixture accurate to within 2 percent. Prepared standards must be replaced each day of use unless it is demonstrated that degradation does not occur during storage.

7.4 Mixtures with non-Reference Compound Gases. Calibrations may be performed using a compound other than the reference compound. In this case, a conversion factor must be determined for the alternative compound such that the resulting meter readings during source surveys can be converted to reference compound results.

8.0 Sample Collection, Preservation, Storage, and Transport

8.1 Instrument Performance Evaluation. Assemble and start up the instrument according to the manufacturer's instructions for recommended warm-up period and preliminary adjustments.

8.1.1 Response Factor. A response factor must be determined for each compound that is to be measured, either by testing or from reference sources. The response factor tests are required before placing the analyzer into service, but do not have to be repeated at subsequent intervals.

8.1.1.1 Calibrate the instrument with the reference compound as specified in the applicable regulation. Introduce the calibration gas mixture to the analyzer and record the observed meter reading. Introduce zero gas until a stable reading is obtained. Make a total of three measurements by alternating between the calibration gas and zero gas. Calculate the response factor for each repetition and the average response factor.

8.1.1.2 The instrument response factors for each of the individual VOC to be measured shall be less than 10 unless otherwise specified in the applicable regulation. When no instrument is available that meets this specification when calibrated with the reference VOC specified in the applicable regulation, the available instrument may be calibrated with one of the VOC to be measured, or any other VOC, so long as the instrument then has a response factor of less than 10 for each of the individual VOC to be measured.

8.1.1.3 Alternatively, if response factors have been published for the compounds of interest for the instrument or detector type, the response factor determination is not required, and existing results may be referenced. Examples of published response factors for flame ionization and catalytic oxidation detectors are included in References 1–3 of Section 17.0.

8.1.2 Calibration Precision. The calibration precision test must be completed prior to placing the analyzer into service and at subsequent 3-month intervals or at the next use, whichever is later.

8.1.2.1 Make a total of three measurements by alternately using zero gas and the specified calibration gas. Record the meter readings. Calculate the average algebraic difference between the meter readings and the known value. Divide this average difference by the known calibration value and multiply by 100 to express the resulting calibration precision as a percentage.

8.1.2.2 The calibration precision shall be equal to or less than 10 percent of the calibration gas value.

8.1.3 Response Time. The response time test is required before placing the instrument into service. If a modification to the sample pumping system or flow configuration is made that would change the response time, a new test is required before further use.

8.1.3.1 Introduce zero gas into the instrument sample probe. When the meter reading has stabilized, switch quickly to the specified calibration gas. After switching, measure the time required to attain 90 percent of the final stable reading. Perform this test sequence three times and record the results. Calculate the average response time.

8.1.3.2 The instrument response time shall be equal to or less than 30 seconds. The instrument pump, dilution probe (if any), sample probe, and probe filter that will be used during testing shall all be in place during the response time determination.

8.2 Instrument Calibration. Calibrate the VOC monitoring instrument according to Section 10.0.

8.3 Individual Source Surveys.

8.3.1 Type I—Leak Definition Based on Concentration. Place the probe inlet at the surface of the component interface where leakage could occur. Move the probe along the interface periphery while observing the instrument readout. If an increased meter reading is observed, slowly sample the interface where leakage is indicated until the maximum meter reading is obtained. Leave the probe inlet at this maximum reading location for approximately two times the instrument response time. If the maximum observed meter reading is greater than the leak definition in the applicable regulation, record and report the results as specified in the regulation reporting requirements. Examples of the application of this general technique to specific equipment types are:

8.3.1.1 Valves. The most common source of leaks from valves is the seal between the stem and housing. Place the probe at the interface where the stem exits the packing gland and sample the stem circumference. Also, place the probe at the interface of the packing gland take-up flange seat and sample the periphery. In addition, survey valve housings of multipart assembly at the surface of all interfaces where a leak could occur.

8.3.1.2 Flanges and Other Connections. For welded flanges, place the probe at the outer edge of the flange-gasket interface and sample the circumference of the flange. Sample other types of nonpermanent joints (such as threaded connections) with a similar traverse.

8.3.1.3 Pumps and Compressors. Conduct a circumferential traverse at the outer surface of the pump or compressor shaft and seal interface. If the source is a rotating shaft, position the probe inlet within 1 cm of the shaft-seal interface for the survey. If the housing configuration prevents a complete traverse of the shaft periphery, sample all accessible portions. Sample all other joints on the pump or compressor housing where leakage could occur.

8.3.1.4 Pressure Relief Devices. The configuration of most pressure relief devices prevents sampling at the sealing seat interface. For those devices equipped with an enclosed extension, or horn, place the probe inlet at approximately the center of the exhaust area to the atmosphere.

8.3.1.5 Process Drains. For open drains, place the probe inlet at approximately the center of the area open to the atmosphere. For covered drains, place the probe at the surface of the cover interface and conduct a peripheral traverse.

8.3.1.6 Open-ended Lines or Valves. Place the probe inlet at approximately the center of the opening to the atmosphere.

8.3.1.7 Seal System Degassing Vents and Accumulator Vents. Place the probe inlet at approximately the center of the opening to the atmosphere.

8.3.1.8 Access door seals. Place the probe inlet at the surface of the door seal interface and conduct a peripheral traverse.

8.3.2 Type II—"No Detectable Emission". Determine the local ambient VOC concentration around the source by moving the probe randomly upwind and downwind at a distance of one to two meters from the source. If an interference exists with this determination due to a nearby emission or leak, the local ambient concentration may be determined at distances closer to the source, but in no case shall the distance be less than 25 centimeters. Then move the probe inlet to the surface of the source and determine the concentration as outlined in Section 8.3.1. The difference between these concentrations determines whether there are no detectable emissions. Record and report the results as specified by the regulation. For those cases where the regulation requires a specific device installation, or that specified vents be ducted or piped to a control device, the existence of these conditions shall be visually confirmed. When the regulation also requires that no detectable emissions exist, visual observations and sampling surveys are required. Examples of this technique are:

8.3.2.1 Pump or Compressor Seals. If applicable, determine the type of shaft seal. Perform a survey of the local area ambient VOC concentration and determine if detectable emissions exist as described in Section 8.3.2.

8.3.2.2 Seal System Degassing Vents, Accumulator Vessel Vents, Pressure Relief Devices. If applicable, observe whether or not the applicable ducting or piping exists. Also, determine if any sources exist in the ducting or piping where emissions could occur upstream of the control device. If the required ducting or piping exists and there are no sources where the emissions could be vented to the atmosphere upstream of the control device, then it is presumed that no detectable emissions are present. If there are sources in the ducting or piping where emissions could be vented or sources where leaks could occur, the sampling surveys described in Section 8.3.2 shall be used to determine if detectable emissions exist.

8.3.3 Alternative Screening Procedure.

8.3.3.1 A screening procedure based on the formation of bubbles in a soap solution that is sprayed on a potential leak source may be used for those sources that do not have continuously moving parts, that do not have surface temperatures greater than the boiling point or less than the freezing point of the soap solution, that do not have open areas to the atmosphere that the soap solution cannot bridge, or that do not exhibit evidence of liquid leakage. Sources that have these conditions present must be surveyed using the instrument technique of Section 8.3.1 or 8.3.2.

8.3.3.2 Spray a soap solution over all potential leak sources. The soap solution may be a commercially available leak detection solution or may be prepared using concentrated detergent and water. A pressure sprayer or squeeze bottle may be used to dispense the solution. Observe the potential leak sites to determine if any bubbles are formed. If no bubbles are observed, the source is presumed to have no detectable emissions or leaks as applicable. If any bubbles are observed, the instrument techniques of Section 8.3.1 or 8.3.2 shall be used to determine if a leak exists, or if the source has detectable emissions, as applicable.

9.0 Quality Control

Section	Quality control measure	Effect
8.1.2	Instrument calibration precision check	Ensure precision and accuracy, respectively, of instrument response to standard.
10.0	Instrument calibration	

10.0 Calibration and Standardization

10.1 Calibrate the VOC monitoring instrument as follows. After the appropriate warm-up period and zero internal calibration procedure, introduce the calibration gas into the instrument sample probe. Adjust the instrument meter readout to correspond to the calibration gas value.

Note: If the meter readout cannot be adjusted to the proper value, a malfunction of the analyzer is indicated and corrective actions are necessary before use.

FOREWORD

The EPA's protocol for estimating equipment leak emissions is the result of detailed information gathering and data analysis. The protocol was written to provide a thorough understanding of acceptable approaches to generating process unit-specific emission estimates. In preparing this document, the EPA has encouraged knowledgeable individuals in industry and the regulatory community to provide comments.

The EPA has put forth considerable effort to make this document as comprehensive as possible. However, it should be understood that not all details and topics pertaining to equipment leaks could feasibly be included in this document. Additionally, it should be understood that the procedures presented in this document are not necessarily suitable for all applications. There will be cases where it will be necessary for the user of the document to make a professional judgement as to the appropriate technical approach for collecting and analyzing data used to estimate equipment leak emissions.

Additional data on equipment leak emissions continues to be collected. It is the intent of the EPA to periodically update this document after analysis of the data warrants such an update. For example, data recently collected in the petroleum industry has been used to revise the existing refinery correlations, which are based on data collected in the late 1970s. Furthermore, as new techniques for collecting and analyzing data are developed, they will be included in updated versions of this document.

Mention of any manufacturer or company name within this document does not represent endorsement by the EPA.

4.0 MASS EMISSION SAMPLING

4.1 INTRODUCTION

This chapter describes the procedures for "bagging" equipment to measure mass emissions of organic compounds. An equipment component is bagged by enclosing the component to collect leaking vapors. Measured emission rates from bagged equipment coupled with screening values can be used to develop unit-specific screening value/mass emission rate correlation equations. Unit-specific correlations can provide precise estimates of mass emissions from equipment leaks at the process unit. However, it is recommended that unit-specific correlations are only developed in cases where the existing EPA correlations do not give reasonable mass emission estimates for the process unit. The focus of the chapter is on bagging equipment containing organic compounds, but similar procedures can be applied to bag equipment containing inorganic compounds as long as there are comparable analytical techniques for measuring the concentration of the inorganic compound.

This chapter is divided into four sections. In section 4.2, the methods for bagging equipment are discussed. Considerations for bagging each equipment type are discussed in section 4.3. In section 4.4, techniques used in the laboratory analysis of bagged samples are discussed. Section 4.4 also includes a description of a rigorous calibration procedure for the portable monitoring device that must be followed. Finally, in section 4.5, quality assurance and quality control (QA/QC) guidelines are provided.

4.2 SAMPLING METHODS

The emission rate from an equipment component is measured by bagging the component--that is, isolating the component from ambient air to collect any leaking compound(s). A tent (i.e., bag) made of material impermeable to the compound(s) of interest is constructed around the leak interface of the piece of equipment. A known rate of carrier gas is induced through the bag and a sample of the gas from the bag is collected and analyzed to determine the concentration (in parts per million by volume [ppmv]) of leaking material. The concentration is measured using laboratory instrumentation and procedures. Mass emissions are calculated based on the measured concentration and the flow rate of carrier gas through the bag.

In some cases, it may be necessary to collect liquid leaking from a bagged equipment piece. Liquid can either be dripping from the equipment piece prior to bagging, and/or be formed as condensate within the bag. If liquid accumulates in the bag, then the bag should be configured so that there is a low point to collect the liquid. The time in which the liquid accumulates should be recorded. The accumulated liquid should then be taken to the laboratory and transferred to a graduated cylinder to measure the volume of organic material. Based on the volume of organic material in the cylinder (with the volume of water or nonorganic material subtracted out), the density of the organic material, and the time in which the liquid accumulated, the organic liquid leak rate can be calculated. Note that the density can be assumed to be equivalent to the density of organic material in the equipment piece, or, if sufficient volume is collected, can be measured using a hydrometer. It should be noted that in some cases condensate may form a light coating on the inside surface of the bag, but will not accumulate. In these cases, it can be assumed that an equilibrium between condensation and evaporation has been reached and that the vapor emissions are equivalent to total emissions from the source.

When bagging an equipment piece, the enclosure should be kept as small as practical. This has several beneficial effects:

- The time required to reach equilibrium is kept to a minimum;
- The time required to construct the enclosure is minimized;
- A more effective seal results from the reduced seal area; and
- Condensation of heavy organic compounds inside the enclosure is minimized or prevented due to reduced residence time and decreased surface area available for heat transfer.

Two methods are generally employed in sampling source enclosures: the vacuum method and the blow-through method. Both methods involve enclosing individual equipment pieces with a bag and setting up a sampling train to collect two samples of leaking vapors to be taken to the laboratory for analysis. Both methods require that a screening value be obtained from the equipment piece prior to and after the equipment piece is enclosed. The methods differ in the ways in which the carrier gas is conveyed through the bag. In the vacuum method, a vacuum pump is used to pull air through the bag. In the blow-through method, a carrier gas such as nitrogen (or other inert gas) is blown into the bag.

In general, the blow-through method has advantages over the vacuum method. These advantages are as follows.

(1) The blow-through method is more conducive to better mixing in the bag.

(2) The blow-through method minimizes ambient air in the bag and thus reduces potential error associated with background organic compound concentrations. (For this reason the blow-through method is especially preferable when measuring the leak rate from components with zero or very low screening values.)

(3) The blow-through method minimizes oxygen concentration in the bag (assuming air is not used as the carrier gas) and the risk of creating an explosive environment.

(4) In general, less equipment is required to set up the blow-through method sampling train.

However, the blow-through method does require a carrier gas source, and preferably the carrier gas should be inert and free of any organic compounds and moisture. The vacuum method does not require a special carrier gas.

Details of the sampling train of each of these bagging methods are discussed in sections 4.2.1 and 4.2.2, respectively. These sections also contain summaries of the steps of the sampling procedure for each method. For both methods, the approach described above for collecting and measuring liquid leak rates can be utilized. In addition to the sampling descriptions presented in the following sections, the quality control and assurance guidelines presented in section 4.5 must also be followed when bagging equipment.

4.2.1 Vacuum Method

The sampling train used in the vacuum method is depicted in figure 4-1. The train can be mounted on a portable cart, which can be moved around the process unit from component to component. The major equipment items in the sampling train are the vacuum pump used to draw air through the system, and the dry gas meter used to measure the flow rate of gas through the train. In previous studies that the EPA conducted, a 4.8-cubic feet per minute Teflon® ring piston-type vacuum pump equipped with a 3/4-horsepower, air-driven motor was used. Other equipment that may be used in the train includes valves, copper and stainless steel tubing, Teflon® tubing and tape, thermometer, pressure-reading device, liquid collection device, and air-driven diaphragm sampling pumps. It also may be necessary to use desiccant preceding the dry gas meter to remove any moisture.

The bag is connected by means of a bulkhead fitting and Teflon® tubing to the sampling train. A separate line is connected from the bag to a pressure-reading device to allow continuous monitoring of the pressure inside the bag. If a significant vacuum exists inside the bag when air is being pulled through, a hole is made in the opposite side of the bag from the outlet to the sampling train. This allows air to enter the bag more easily and, thus, reduces the vacuum in the enclosure. However, it is important to maintain a vacuum in the bag, since VOC could be lost through the hole if the bag became pressurized.

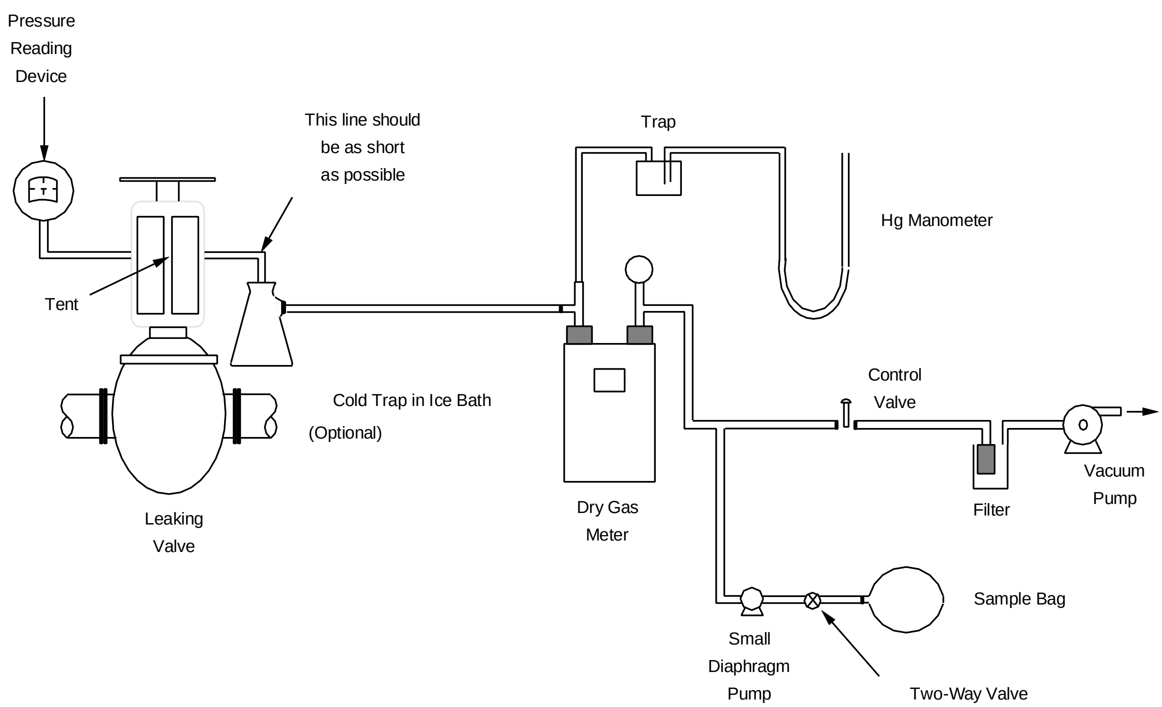

Figure 4-1. Sampling train for bagging a source using the vacuum method.

In practice, it has been found that only a very slight vacuum (0.1 inches of water) is present in the bag during most of the sampling, even in the absence of a hole through the bag wall. Sufficient air enters around the seals to prevent the development of a significant vacuum in the bag. A small diaphragm sampling pump can be used to collect two samples into sample bags or canisters, which are then transported to the laboratory for analysis.

The diaphragm pump can also be used to collect a background sample of the ambient air near the bagged component. The concentration in the background bag is subtracted from the average concentration in the sample bags when calculating the leak rate. Often this correction is insignificant (particularly for components with high leak rates or in cases where there is no detectable volatile organic compound (VOC) concentration measured by the portable monitoring device), and collection of a background bag is optional. However, in some cases collection of a background bag is important so that emission rates are not biased high.

Any liquid that accumulates in the bag should be collected using the approach described in section 4.2. Note that if there is a concern that condensation will occur in equipment downstream from the bag outlet, a cold trap can be placed as close to the bag outlet as possible to remove water or heavy organic compounds that may condense downstream. Any organic condensate that collects in the cold trap must be measured to calculate the total leak rate.

The flow rate through the system can be varied by throttling the flow with a control valve immediately upstream of the vacuum pump. Typical flow rates are approximately 60 liters per minute (ℓ/min) or less. A good flow rate to use is one in which a balance can be found between reaching equilibrium conditions and having a high enough concentration of organic compounds in the bag outlet to accurately measure the concentration in the laboratory. As the flow rate is decreased, the concentration of organic compounds increases in the gas flowing through the sampling system. The flow rate should be adjusted to avoid any operations with an explosive mixture of organic compounds in air. It may also be possible to increase the flow rate in order to minimize liquid condensation in the bag.

The flow rate should be set to a constant rate and kept at that rate long enough for the system to reach equilibrium. To determine if equilibrium conditions have been reached, a portable monitoring device can be used to indicate if the outlet concentration has stabilized.

It is not recommended that the vacuum method be used to measure the leak rate from equipment that have low screening values (approximately 10 ppmv or less), because considerable error can be introduced due to the background organic concentration in the ambient air that is pulled through the bag.

In summary, the vacuum sampling procedure consists of the following steps.

(1) Determine the composition of material in the designated equipment component, and the operating conditions of the component.

(2) Obtain and record a screening value with the portable monitoring instrument.

(3) Cut a bag from appropriate material (see section 4.3) that will easily fit over the equipment component.

(4) Connect the bag to the sampling train.

(5) If a cold trap is used, immerse the trap in an ice bath.

(6) Note the initial reading of the dry gas meter.

(7) Start the vacuum pump and a stopwatch simultaneously. Make sure a vacuum exists within the bag.

(8) Record the temperature and pressure at the dry gas meter.

(9) Observe the VOC concentration at the vacuum pump exhaust with the monitoring instrument. Make sure concentration stays below the lower explosive limit.

(10) Record the temperature, pressure, dry gas meter reading, outlet VOC concentration and elapsed time every 2 to 5 minutes (min).

(11) Collect 2 gas samples from the discharge of the diaphragm sampling pump when the outlet concentration stabilizes (i.e., the system is at equilibrium).

(12) Collect a background bag (optional).

(13) Collect any liquid that accumulated in the bag as well as in the cold trap (if used) in a sealed container.

(14) Take a final set of readings and stop the vacuum pump.

(15) Transport all samples to the laboratory, along with the data sheet.

(16) Remove the bag.

(17) Rescreen the source with the portable monitoring instrument and record.

Based on the data collected in the steps described above, mass emissions are calculated using the equation presented in table 4-1.

4.2.2 Blow-Through Method

The sampling train for the blow-through method is presented in figure 4-2. The temperature and oxygen concentrations are measured inside the bag with a thermocouple (or thermometer) and an oxygen/combustible gas monitor. The carrier gas is metered into the bag through one or two tubes (two tubes provide for better mixing) at a steady rate throughout the sampling period. The flow rate of the carrier gas is monitored in a gas rotameter calibrated to the gas. Typical flow rates are approximately 60 ℓ/min or less. It is preferable to use an inert gas such as nitrogen for the blow-through method so as to minimize the risk of creating an explosive environment inside the bag. Also, the carrier gas should be free of any organic compounds and moisture. The pressure in the bag should never exceed 1 pound per square inch gauge (psig).

The flow rate through the bag can be varied by adjusting the carrier gas regulator. As mentioned in section 4.2.1, a good flow rate to use is one in which a balance can be found between reaching equilibrium conditions and having a high enough

TABLE 4-1. CALCULATION PROCEDURES FOR LEAK RATE WHEN USING THE VACUUM METHOD

$$\text{Leak Rate (kg/hr)} = \frac{9.63 \times 10^{-10}\,(Q)(MW)(GC)(P)}{T + 273.15} + \frac{(\rho)(V_L)}{16.67(t)}$$

where:

9.63×10^{-10}	=	A conversion factor using the gas constant: $\frac{°K \times 10^6 \times \text{kg-mol} \times \text{min}}{\ell \times \text{hour} \times \text{mmHg}}$;
Q	=	Flow rate out of bag (ℓ/min);
MW[a]	=	Molecular weight of organic compound(s) in the sample bag[c] or alternatively in the process stream contained within the equipment piece being bagged (kg/kg-mol);
GC[b]	=	Sample bag organic compound concentration (ppmv) minus background bag organic compound concentration[c] (ppmv);
P	=	Absolute pressure at the dry gas meter (mmHg);
T	=	Temperature at the dry gas meter (°C);
ρ	=	Density of organic liquid collected (g/mℓ);
V_L	=	Volume of liquid collected (mℓ);
16.67	=	A conversion factor to adjust term to units of kilograms per hour (g × hr)/(kg × min)
t	=	Time in which liquid is collected (min); and

[a]For mixtures calculate MW as:

$$= \sum_{i=1}^{n} MW_i\, X_i \;/\; \sum_{i=1}^{n} X_i$$

where:

MW_i = Molecular weight of organic compound i;
X_i = Mole fraction of organic compound i; and
n = Number of organic compounds in mixture.

[b]For mixtures, the value of GC is the total concentration of all the organic compounds in the mixture.

[c]Collection of a background bag is optional. If a background bag is not collected, assume the background concentration is zero.

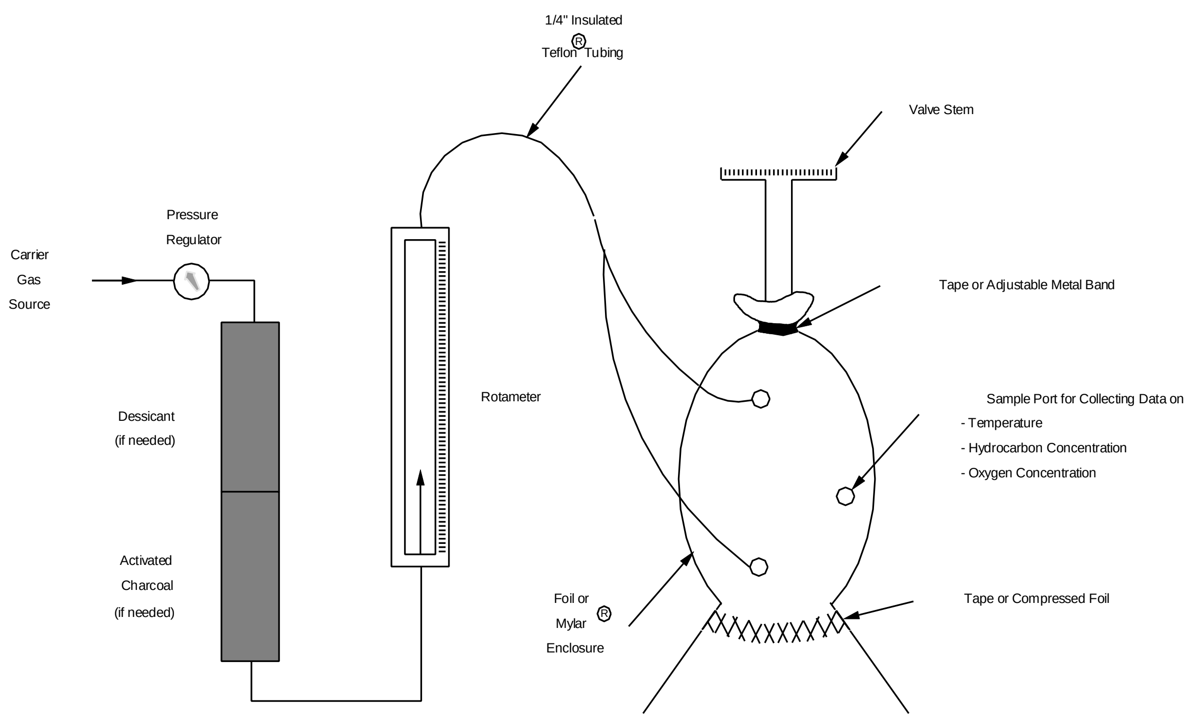

Figure 4-2. Equipment Required for the Blow-Through Sampling Technique

concentration of organic compounds in the bag outlet to accurately measure the concentration in the laboratory. Adjustments to the flow rate may also help minimize liquid condensation in the bag. Any liquid that does accumulate in the bag should be collected using the approach described in section 4.2.

The carrier gas flow rate should be set to a constant rate and kept at that rate long enough for the system to reach equilibrium. In addition to the carrier gas flow through the bag, some ambient air may enter the bag if it is not airtight. The oxygen measurements are used to determine the flow of ambient air through the bag. The oxygen measurements are also an indication of the quality of the bagging procedure (the lower the oxygen concentration the better). Once oxygen concentration falls below 5 percent, the portable monitoring instrument is used to check organic compound concentrations at several locations within the bag to ensure that the bag contents are at steady state.

Once the bag contents are at steady state, two gas samples are drawn out of the bag for laboratory analysis using a portable sampling pump. It may also be necessary to collect a background bag sample, particularly if the source had screened at zero and if there is still a detectable level of oxygen in the bag. However, collection of a background bag is optional.

In summary, the blow-through method consists of the following steps, which assume nitrogen is used as the carrier gas.

(1) Determine the composition of the material in the designated equipment component, and the operating conditions of the component.

(2) Screen the component using the portable monitoring instrument.

(3) Cut a bag that will easily fit over the equipment component.

(4) Connect tubing from the nearest nitrogen source to a rotameter stand.

(5) Run tubing from the rotameter outlet to a "Y" that splits the nitrogen flow into two pieces of tubing and insert the tubes into openings located on either side of the bag.

(6) Turn on the nitrogen flow and regulate it at the rotameter to a constant rate and record the time.

(7) After the nitrogen is flowing, wrap aluminum foil around those parts of the component where air could enter the bag-enclosed volume.

(8) Use duct tape, wire, and/or rope to secure the bag to the component.

(9) Put a third hole in the bag roughly equidistant from the two carrier gas-fed holes.

(10) Measure the oxygen concentration in the bag by inserting the lead from an oxygen meter into the third hole. Adjust the bag (i.e., modify the seals at potential leak points) until the oxygen concentration is less than 5 percent.

(11) Measure the temperature in the bag.

(12) Check the organic compound concentration at several points in the bag with the portable monitoring instrument to ensure that carrier gas and VOC are well mixed throughout the bag.

(13) Collect samples in sample bags or canisters by drawing a sample out of the bag with a portable sampling pump.

(14) Collect a background bag (optional).

(15) Remove the bag and collect any liquid that accumulated in the bag in a sealed container. Note the time over which the liquid accumulated.

(16) Rescreen the source.

Table 4-2 gives equations used to calculate mass emission rates when using the blow-through method. An adjustment is provided for the leak rate equation in table 4-2 to account for the total flow through the bag. This adjustment is recommended and represents an improvement over previous versions

TABLE 4-2. CALCULATION PROCEDURES FOR LEAK RATE WHEN USING THE BLOW-THROUGH METHOD

$$\text{Leak Rate (kg/hr)} = \left(\frac{1.219 \times 10^{-5}\,(Q)\,(MW)\,(GC)}{T + 273.15} + \frac{(\rho)\,(V_L)}{16.67\,(t)}\right) \times \left(\frac{10^6\,\text{ppmv}}{10^6\,\text{ppmv} - GC}\right)$$

where:

1.219×10^{-5} = A conversion factor taking into account the gas constant and assuming a pressure in the tent of 1 atmosphere:

$$\frac{{}^{o}K \times 10^6 \times \text{kg-mol}}{m^3};$$

Q = flow rate out of tent (m^3/hr);

$$= \frac{N_2 \text{ Flow Rate } (\ell/\text{min})}{1 - [\text{Tent Oxygen Conc. (volume \%)}/21]} \times \frac{[0.06\ (m^3/\text{min})]}{(\ell/\text{hr})}$$

MW[a] = Molecular weight of organic compounds in the sample bag or alternatively in the process stream contained within the equipment piece being bagged (kg/kg-mol);

GC[b] = Sample bag organic compound concentration (ppmv), corrected for background bag organic compound concentration (ppmv);[c]

T = Temperature in tent (°C);

ρ = Density of organic liquid collected (g/mℓ);

V_L = Volume of liquid collected (mℓ);

16.67 = A conversion factor to adjust term to units of Kilograms per hour (g × hr)/(kg × min); and

t = Time in which liquid is collected (min).

[a]For mixtures calculate MW as:

$$= \sum_{i=1}^{n} MW_i\, X_i \;/\; \sum_{i=1}^{n} X_i$$

where:

MW_i = Molecular weight of organic compound i;

TABLE 4-2. CALCULATION PROCEDURES FOR LEAK RATE WHEN USING THE BLOW-THROUGH METHOD (Continued)

X_i = Mole fraction of organic compound i; and
n = Number of organic compounds in mixture.

[b]For mixtures, the value of GC is the total concentration of all the organic compounds in the mixture.

[c]Collection of a background bag is optional. If a background bag is not collected, assume the background concentration is zero. To correct for background concentration, use the following equation:

$$\underset{(\text{ppmv})}{GC} = SB - \left(\frac{TENT}{21} \times BG\right)$$

where:

SB = Sample bag concentration (ppmv);
TENT = Tent oxygen concentration (volume %); and
BG = Background bag concentration (ppmv)

of this document for quantifying mass emissions from the blow through method.

4.3 SOURCE ENCLOSURE

In this section, choosing a bagging material and the approach for bagging specific equipment types are discussed. An important criteria when choosing the bagging material is that it is impermeable to the specific compounds being emitted from the equipment piece. This criteria is also applicable for sample gas bags that are used to transport samples to the laboratory. A bag stability test over time similar to the Flexible Bag Procedure described in section 5.3.2 of the EPA method 18 is one way to check the suitability of a bagging material.[1] After a bag has been used, it must be purged. Bags containing residual organic compounds that cannot be purged should be discarded. Mylar®, Tedlar®, Teflon®, aluminum foil, or aluminized Mylar® are recommended potential bagging materials. The thickness of the bagging material can range from 1.5 to 15 millimeters (mm), depending on the bagging configuration needed for the type of equipment being bagged, and the bagging material. Bag construction for individual sources is discussed in sections 4.3.1 through 4.3.5. For convenience, Mylar® will be used as an example of bagging material in the following discussions.

4.3.1 Valves

When a valve is bagged, only the leak points on the valve should be enclosed. Do not enclose surrounding flanges. The most important property of the valve that affects the type of enclosure selected for use is the metal skin temperature where the bag will be sealed. At skin temperatures of approximately 200 ^{o}C or less, the valve stem and/or stem support can be wrapped with 1.5- to 2.0-mm Mylar® and sealed with duct tape at each end and at the seam. The Mylar® bag must be constructed to enclose the valve stem seal and the packing gland seal.

When skin temperatures are in excess of 200 ^{o}C, a different method of bagging the valve should be utilized. Metal bands, wires, or foil can be wrapped around all hot points that would be in contact with the Mylar® bag material. Seals are then made against the insulation using duct tape or adjustable metal bands of stainless steel. At extremely high temperatures, metal foil can be used as the bagging material and metal bands used to form seals. At points where the shape of the equipment prevent a satisfactory seal with metal bands, the foil can be crimped to make a seal.

4.3.2 Pumps and Agitators

As with valves, a property of concern when preparing to sample a pump or agitator is the metal skin temperature at areas or points that are in contact with the bag material. At skin temperatures below 200 ^{o}C, Mylar® plastic and duct tape are satisfactory materials for constructing a bag around a pump or agitator seal. If the temperature is too high or the potential points of contact are too numerous to insulate, an enclosure made of aluminum foil can be constructed. This enclosure is sealed around the pump and bearing housing using silicone fabric insulting tape, adjustable metal bands, or wire.

The configuration of the bag will depend upon the type of pump. Most centrifugal pumps have a housing or support that connects the pump drive (or bearing housing) to the pump itself. The support normally encloses about one-half of the area between the pump and drive motor, leaving open areas on the sides. The pump can be bagged by cutting panels to fit these open areas. These panels can be made using thicker bagging material such as 14-mm Mylar®. In cases where supports are absent or quite narrow, a cylindrical enclosure around the seal can be made so that it extends from the pump housing to the motor or bearing support. As with the panels, this enclosure should be made with thicker bagging material to provide strength and rigidity.

Reciprocating pumps can present a somewhat more difficult bagging problem. If supports are present, the same type of two-panel Mylar® bag can be constructed as that for centrifugal pumps. In many instances, however, sufficiently large supports are not provided, or the distance between pump and driver is relatively long. In these cases, a cylindrical enclosure as discussed above can be constructed. If it is impractical to extend the enclosure all the way from the pump seal to the pump driver, a seal can be made around the reciprocating shaft. This can usually be best completed by using heavy aluminum foil and crimping it to fit closely around the shaft. The foil is attached to the Mylar® plastic of the enclosure and sealed with the duct tape.

In cases where liquid is leaking from a pump, the outlet from the bag to the sampling train should be placed at the top of the bag and as far away from spraying leaks as practical. A low point should be formed in the bag to collect the liquid so that the volume of the liquid can be measured and converted to a mass rate.

4.3.3 Compressors

In general, the same types of bags that are suitable for pumps can be directly applied to compressors. However, in some cases, compressor seals are enclosed and vented to the atmosphere at a high-point vent. If the seals are vented to a high-point vent, this vent line can be sampled. A Mylar® bag can be constructed and sealed around the outlet of the vent and connected to the sampling train. If the high-point vents are inaccessible, the vent lines from the compressor seal enclosures can be disconnected at some convenient point between the compressor and the normal vent exit. Sampling is then conducted at this intermediate point. In other cases, enclosed compressor seals are vented by means of induced draft blowers or fans. In these cases, if the air flow rate is know or can be determined, the outlet from the blower/fan can be sampled to determine the emission rate.

4.3.4 Connectors

In most cases, the physical configurations of connectors lend themselves well to the determination of leak rates. The same technique can be used for a connector whether it is a flanged or a threaded fitting. To bag a connector with a skin temperature below 200 ^{o}C, a narrow section of Mylar® film is constructed to span the distance between the two flange faces or the threaded fitting of the leaking source. The Mylar® is attached and sealed with duct tape. When testing connectors with skin temperatures above 200 ^{o}C, the outside perimeter of both sides of the connector are wrapped with heat-resistant insulating tape. Then, a narrow strip of aluminum foil can be used to span the distance between the connection. This narrow strip of foil can be sealed against the insulating tape using adjustable bands of stainless steel.

4.3.5 Relief Valves

Relief devices in gas/vapor service generally relieve to the atmosphere through a large-diameter pipe that is normally located at a high point on the process unit that it serves. The "horns" can be easily bagged by placing a Mylar® plastic bag over the opening and sealing it to the horn with duct tape. Because may of these devices are above grade level, accessibility to the sampling train may be limited or prevented. It is sometimes possible to run a long piece of tubing from the outlet connection on the bag to the sampling train located at grade level or on a stable platform.

As discussed previously in section 3.0, the purpose of pressure relief devices makes them inherently dangerous to sample, especially over a long period of time. If these equipment are to be sampled for mass emissions, special care and precautions should be taken to ensure the safety of the personnel conducting the field sampling.

4.4 ANALYTICAL TECHNIQUES

The techniques used in the laboratory analysis of the bagged samples will depend on the type of processes sampled. The following sections describe the analytical instrumentation and calibration, and analytical techniques for condensate. These are guidelines and are not meant to be a detailed protocol for the laboratory personnel. Laboratory personnel should be well-versed in the analysis of organic compound mixtures and should design their specific analyses to the samples being examined.

Also discussed is the calibration protocol for the portable monitoring instrument. When bagging data are collected, it is

16. ABSTRACT

The report presents standard protocols for estimating mass emissions from equipment leaks. Different approaches for estimating equipment leak emissions are described and several topics relevant to estimating equipment leak emissions (such as speciating emissions) are addressed. Information on how to perform a screening survey at a process unit is presented. Information on how a process unit can collect equipment leak rate data by enclosing individual equipment pieces and measuring mass emissions is provided. Also, information if provided that can be used to estimate the control efficiency of equipment leak control techniques. The document will help facilities generate accurate plant-specific equipment leak emission estimates.

Sampling Procedure

Step 1
Perform pre-test quality control checks,

Step 2
Perform leak checks and capture information:

- System Leak Check (L/min)
- Use a calibrated FID to take a measurement (ppmv) of the system background
- Use a calibrated FID to take a measurement (ppmv) of the sample tubing background
- Sorbent Tube Leak Check (inch Hg/min)
- Complete standardized field data sheet
    - Equipment type
    - Equipment subtype
    - Line size
    - Stream phase (confirm heavy liquid)
    - Barometric pressure
    - Ambient temperature
    - Stream temperature
    - Component temperature
    - Stream description
    - Component Identification
    - Unit Identification
    - Date
    - Bagging Team
    - Screening Instrument Identification
    - Sample Pump A Identification
    - Sample Pump B Identification
    - Stream Pressure

Step 3

- Follow U.S. EPA Method 21 to identify the location of maximum leak.
- Record the FID measurement at eight seconds.
- Record the maximum FID measurement and the time needed to reach that value.

Step 4

- If the component was wet or dirty where the bag would be secured, the surface was wiped dry or clean with a cloth, carefully do not disturb the area of the leak.

Step 5

- Enclose component leak using sheets of Mylar and fit 3/8 inch and ¼ inch bulkhead fittings for the vacuum and sample lines, respectively.

Step 6

- Secure Mylar sheets to the component using either duct tape or aluminum foil (for hot or irregular surfaces) and/or high temperature tape to seal against ambient air ingress into the enclosure. Avoid sticking duct tape inside Mylar bag.

Step 7

- Use Teflon tubing to connect the 3/8-inch bulkhead fitting to a sample line attached to a portable bagging cart and the ¼ inch bulkhead fitting to a bag vacuum gauge.

Step 8

- Place the vacuum gauge on a level surface and adjust zero reading, as necessary.

Step 9

- Prepare sample media.
- Perform sorbent tube leak check and document results.

Step 10

- Turn on sample pump
- Verify bag vacuum,
- Record bag and dry gas meter pressure measurements and bag temperature.

Step 11

- Record sample pump volumes prior to start of sampling.
- Once total hydrocarbon concentrations have reached equilibrium, start sampling.

Step 12

- Use a stopwatch to measure the system flow rate at the dry gas meter (or rotary gas meter).
- Monitor total hydrocarbon concentration levels within the bag and at the outlet(s) of sample pump(s).
- Record bag and dry gas meter pressure measurements and bag temperature.

Step 13

- Stop sampling after sample run length (12 minutes) and record sample pump volumes.
- Remove sample tubes, place end caps on tubes, and place in a portable ice chest to maintain sample temperatures.

Step 14

- Turn off main pump and remove bag while checking for any accumulated condensate.

Step 15

- Take an additional screening measurement of the component, recording the measured values at eight seconds, and final concentrations (noting time to reach final concentration).

APPENDIX A-3
Laboratory Methodology

EPA Method 18

METHOD 18—MEASUREMENT OF GASEOUS ORGANIC COMPOUND EMISSIONS BY GAS CHROMATOGRAPHY

NOTE: This method is not inclusive with respect to specifications (*e.g.*, equipment and supplies) and procedures (*e.g.*, sampling and analytical) essential to its performance. Some material is incorporated by reference from other methods in this part. Therefore, to obtain reliable results, persons using this method should have a thorough knowledge of at least the following additional test methods: Method 1, Method 2, Method 3.

NOTE: This method should not be attempted by persons unfamiliar with the performance characteristics of gas chromatography, nor by those persons who are unfamiliar with source sampling. Particular care should be exercised in the area of safety concerning choice of equipment and operation in potentially explosive atmospheres.

1.0 Scope and Application

1.1 Analyte. Total gaseous organic compounds.

1.2 Applicability.

1.2.1 This method is designed to measure gaseous organics emitted from an industrial source. While designed for ppm level sources, some detectors are quite capable of detecting compounds at ambient levels, *e.g.*, ECD, ELCD, and helium ionization detectors. Some other types of detectors are evolving such that the sensitivity and applicability may well be in the ppb range in only a few years.

1.2.2 This method will not determine compounds that (1) are polymeric (high molecular weight), (2) can polymerize before analysis, or (3) have very low vapor pressures at stack or instrument conditions.

1.3 Range. The lower range of this method is determined by the sampling system; adsorbents may be used to concentrate the sample, thus lowering the limit of detection below the 1 part per million (ppm) typically achievable with direct interface or bag sampling. The upper limit is governed by GC detector saturation or column overloading; the upper range can be extended by dilution of sample with an inert gas or by using smaller volume gas sampling loops. The upper limit can also be governed by condensation of higher boiling compounds.

1.4 Sensitivity. The sensitivity limit for a compound is defined as the minimum detectable concentration of that compound, or the concentration that produces a signal-to-noise ratio of three to one. The minimum detectable concentration is determined during the presurvey calibration for each compound.

2.0 Summary of Method

The major organic components of a gas mixture are separated by gas chromatography (GC) and individually quantified by flame ionization, photoionization, electron capture, or other appropriate detection principles. The retention times of each separated component are compared with those of known compounds under identical conditions. Therefore, the analyst confirms the identity and approximate concentrations of the organic emission components beforehand. With this information, the analyst then prepares or purchases commercially available standard mixtures to calibrate the GC under conditions identical to those of the samples. The analyst also determines the need for sample dilution to avoid detector saturation, gas stream filtration to eliminate particulate matter, and prevention of moisture condensation.

3.0 Definitions [Reserved]

4.0 Interferences

4.1 Resolution interferences that may occur can be eliminated by appropriate GC column and detector choice or by shifting the retention times through changes in the column flow rate and the use of temperature programming.

4.2 The analytical system is demonstrated to be essentially free from contaminants by periodically analyzing blanks that consist of hydrocarbon-free air or nitrogen.

4.3 Sample cross-contamination that occurs when high-level and low-level samples or standards are analyzed alternately is best dealt with by thorough purging of the GC sample loop between samples.

4.4 To assure consistent detector response, calibration gases are contained in dry air. To adjust gaseous organic concentrations when water vapor is present in the sample, water vapor concentrations are determined for those samples, and a correction factor is applied.

4.5 The gas chromatograph run time must be sufficient to clear all eluting peaks from the column before proceeding to the next run (in order to prevent sample carryover).

5.0 Safety

5.1 Disclaimer. This method may involve hazardous materials, operations, and equipment. This test method may not address all of the safety problems associated with its use. It is the responsibility of the user of this test method to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to performing this test method. The analyzer users manual should be consulted for specific precautions to be taken with regard to the analytical procedure.

6.0 Equipment and Supplies

6.1 Equipment needed for the presurvey sampling procedure can be found in section 16.1.1.

6.2 Equipment needed for the integrated bag sampling and analysis procedure can be found in section 8.2.1.1.1.

6.3 Equipment needed for direct interface sampling and analysis can be found in section 8.2.2.1.

6.4 Equipment needed for the dilution interface sampling and analysis can be found in section 8.2.3.1.

6.5 Equipment needed for adsorbent tube sampling and analysis can be found in section 8.2.4.1.

7.0 Reagents and Standards

7.1 Reagents needed for the presurvey sampling procedure can be found in section 16.1.2.

8.0 Sample Collection, Preservation, Storage, and Transport

8.2 Final Sampling and Analysis Procedure. Considering safety (flame hazards) and the source conditions, select an appropriate sampling and analysis procedure (Section 8.2.1, 8.2.2, 8.2.3 or 8.2.4). In situations where a hydrogen flame is a hazard and no intrinsically safe GC is suitable, use the flexible bag collection technique or an adsorption technique.

8.2.1 Integrated Bag Sampling and Analysis.

8.2.1.1 Evacuated Container Sampling Procedure. In this procedure, the bags are filled by evacuating the rigid air-tight container holding the bags. Use a field sample data sheet as shown in Figure 18-10. Collect triplicate samples from each sample location.

8.2.1.1.1 Apparatus.

8.2.1.1.1.1 Probe. Stainless steel, Pyrex glass, or Teflon tubing probe, according to the duct temperature, with Teflon tubing of sufficient length to connect to the sample bag. Use stainless steel or Teflon unions to connect probe and sample line.

8.2.1.1.1.2 Quick Connects. Male (2) and female (2) of stainless steel construction.

8.2.1.1.1.3 Needle Valve. To control gas flow.

8.2.1.1.1.4 Pump. Leakless Teflon-coated diaphragm-type pump or equivalent. To deliver at least 1 liter/min.

8.2.1.1.1.5 Charcoal Adsorption Tube. Tube filled with activated charcoal, with glass wool plugs at each end, to adsorb organic vapors.

8.2.1.1.1.6 Flowmeter. 0 to 500-ml flow range; with manufacturer's calibration curve.

8.2.1.1.2 Sampling Procedure. To obtain a sample, assemble the sample train as shown in Figure 18-9. Leak-check both the bag and the container. Connect the vacuum line from the needle valve to the Teflon sample line from the probe. Place the end of the probe at the centroid of the stack or at a point no closer to the walls than 1 in., and start the pump. Set the flow rate so that the final volume of the sample is approximately 80 percent of the bag capacity. After allowing sufficient time to purge the line several times, connect the vacuum line to the bag, and evacuate until the rotameter indicates no flow. Then position the sample and vacuum lines for sampling, and begin the actual sampling, keeping the rate proportional to the stack velocity. As a precaution, direct the gas exiting the rotameter away from sampling personnel. At the end of the sample period, shut off the pump, disconnect the sample line from the bag, and disconnect the vacuum line from the bag container. Record the source temperature, barometric pressure, ambient temperature, sampling flow rate, and initial and final sampling time on the data sheet shown in Figure 18-10. Protect the bag and its container from sunlight. Record the time lapsed between sample collection and analysis, and then conduct the recovery procedure in Section 8.4.2.

8.2.1.2 Direct Pump Sampling Procedure. Follow 8.2.1.1, except place the pump and needle valve between the probe and the bag. Use a pump and needle valve constructed of inert material not affected by the stack gas. Leak-check the system, and then purge with stack gas before connecting to the previously evacuated bag.

8.2.1.3 Explosion Risk Area Bag Sampling Procedure. Follow 8.2.1.1 except replace the pump with another evacuated can (see Figure 18-9a). Use this method whenever there is a possibility of an explosion due to pumps, heated probes, or other flame producing equipment.

8.2.1.4 Other Modified Bag Sampling Procedures. In the event that condensation is observed in the bag while collecting the sample and a direct interface system cannot be used, heat the bag during collection and maintain it at a suitably elevated temperature during all subsequent operations. (Note: Take care to leak-check the system prior to the dilutions so as not to create a potentially explosive atmosphere.) As an alternative, collect the sample gas, and simultaneously dilute it in the bag.

8.2.1.4.1 First Alternative Procedure. Heat the box containing the sample bag to 120 °C (±5 °C). Then transport the bag as rapidly as possible to the analytical area while maintaining the heating, or cover the box with an insulating blanket. In the analytical area, keep the box heated to 120 °C (±5 °C) until analysis. Be sure that the method of heating the box and the control for the heating circuit are compatible with the safety restrictions required in each area.

8.2.1.4.2 Second Alternative Procedure. Prefill the bag with a known quantity of inert gas. Meter the inert gas into the bag according to the procedure for the preparation of gas concentration standards of volatile liquid materials (Section 10.1.2.2), but eliminate the midget impinger section. Take the partly filled bag to the source, and meter the source gas into the bag through heated sampling lines and a heated flowmeter, or Teflon positive displacement pump. Verify the dilution factors before sampling each bag through dilution and analysis of gases of known concentration.

8.2.1.5 Analysis of Bag Samples.

8.2.1.5.1 Apparatus. Same as section 8.1. A minimum of three gas standards are required.

8.2.1.5.2 Procedure.

8.2.1.5.2.1 Establish proper GC operating conditions as described in section 10.2, and record all data listed in Figure 18-7. Prepare the GC so that gas can be drawn through the sample valve. Flush the sample loop with calibration gas mixture, and activate the valve (sample pressure at the inlet to the GC introduction valve should be similar during calibration as during actual sample analysis). Obtain at least three chromatograms for the mixture. The results are acceptable when the peak areas for the three injections agree to within 5 percent of their average. If they do not agree, run additional samples or correct the analytical techniques until this requirement is met. Then analyze the other two calibration mixtures in the same manner. Prepare a calibration curve as described in section 10.2.

8.2.1.5.2.2 Analyze the three source gas samples by connecting each bag to the sampling valve with a piece of Teflon tubing identified with that bag. Analyze each bag sample three times. Record the data in Figure 18-11. If certain items do not apply, use the notation “N.A.” If the bag has been maintained at an elevated temperature as described in section 8.2.1.4, determine the stack gas water content by Method 4. After all samples have been analyzed, repeat the analysis of the mid-level calibration gas for each compound. Compare the average response factor of the pre- and post-test analysis for each compound. If they differ by >5percent, analyze the other calibration gas levels for that compound, and prepare a calibration curve using all the pre- and post-test calibration gas mixture values. If the two response factor averages (pre-and post-test) differ by less than 5 percent from their mean value, the tester has the option of using only the pre-test calibration curve to generate the concentration values.

8.2.1.5.2.3 Analyze the two field audit samples as described in Section 9.2 by connecting each bag containing an audit gas mixture to the sampling valve. Calculate the results; record and report the data to the audit supervisor.

8.2.1.6 Determination of Bag Water Vapor Content. Measure the ambient temperature and barometric pressure near the bag. From a water saturation vapor pressure table, determine and record the water vapor content of the bag as a decimal figure. (Assume the relative humidity to be 100 percent unless a lesser value is known.) If the bag has been maintained at an elevated temperature as described in section 8.2.1.4, determine the stack gas water content by Method 4.

8.2.1.8 Emission Calculations. From the calibration curve described in section 8.2.1.5, select the value of C_s that corresponds to the peak area. Calculate the concentration C_c in ppm, dry basis, of each organic in the sample using Equation 18-5 in section 12.6.

8.2.2 Direct Interface Sampling and Analysis Procedure. The direct interface procedure can be used provided that the moisture content of the gas does not interfere with the analysis procedure, the physical requirements of the equipment can be met at the site, and the source gas concentration falls within the linear range of the detector. Adhere to all safety requirements with this method.

8.2.2.1 Apparatus.

8.2.2.1.1 Probe. Constructed of stainless steel, Pyrex glass, or Teflon tubing as dictated by duct temperature and reactivity of target compounds. A filter or glass wool plug may be needed if particulate is present in the stack gas. If necessary, heat the probe with heating tape or a special heating unit capable of maintaining a temperature greater than 110 °C.

8.2.2.1.2 Sample Lines. 6.4-mm OD (or other diameter as needed) Teflon lines, heat-traced to prevent condensation of material (greater than 110 °C).

8.2.2.1.3 Quick Connects. To connect sample line to gas sampling valve on GC instrument and to pump unit used to withdraw source gas. Use a quick connect or equivalent on the cylinder or bag containing calibration gas to allow connection of the calibration gas to the gas sampling valve.

8.2.2.1.4 Thermocouple Readout Device. Potentiometer or digital thermometer, to measure source temperature and probe temperature.

8.2.2.1.5 Heated Gas Sampling Valve. Of two-position, six-port design, to allow sample loop to be purged with source gas or to direct source gas into the GC instrument.

8.2.2.1.6 Needle Valve. To control gas sampling rate from the source.

8.2.2.1.7 Pump. Leakless Teflon-coated diaphragm-type pump or equivalent, capable of at least 1 liter/minute sampling rate.

8.2.2.1.8 Flowmeter. Of suitable range to measure sampling rate.

8.2.2.1.9 Charcoal Adsorber. To adsorb organic vapor vented from the source to prevent exposure of personnel to source gas.

8.2.2.1.10 Gas Cylinders. Carrier gas, oxygen and fuel as needed to run GC and detector.

8.2.2.1.11 Gas Chromatograph. Capable of being moved into the field, with detector, heated gas sampling valve, column required to complete separation of desired components, and option for temperature programming.

8.2.2.1.12 Recorder/Integrator. To record results.

8.2.2.2 Procedure. Calibrate the GC using the procedures in section 8.2.1.5.2.1. To obtain a stack gas sample, assemble the sampling system as shown in Figure 18-12. Make sure all connections are tight. Turn on the probe and sample line heaters. As the temperature of the probe and heated line approaches the target temperature as indicated on the thermocouple readout device, control the heating to maintain a temperature greater than 110 °C. Conduct a 3-point calibration of the GC by analyzing each gas mixture in triplicate. Generate a calibration curve. Place the inlet of the probe at the centroid of the duct, or at a point no closer to the walls than 1 m, and draw source gas into the probe, heated line, and sample loop. After thorough flushing, analyze the stack gas sample using the same conditions as for the calibration gas mixture. For each run, sample, analyze, and record five consecutive samples. A test consists of three runs (five samples per run times three runs, for a total of fifteen samples). After all samples have been analyzed, repeat the analysis of the mid-level calibration gas for each compound. For each calibration standard, compare the pre- and post-test average response factors (RF) for each compound. If the two calibration RF values (pre- and post-analysis) differ by more than 5 percent from their mean value, then analyze the other calibration gas levels for that compound and determine the stack gas sample concentrations by comparison to both calibration curves (this is done by preparing a calibration curve using all the pre- and post-test calibration gas mixture values.) If the two calibration RF values differ by less than 5 percent from their mean value, the tester has the option of using only the pre-test calibration curve to generate the concentration values. Record this calibration data and the other required data on the data sheet shown in Figure 18-11, deleting the dilution gas information.

NOTE: Take care to draw all samples and calibration mixtures through the sample loop at the same pressure.

8.2.2.3 Determination of Stack Gas Moisture Content. Use Method 4 to measure the stack gas moisture content.

8.2.2.5 Emission Calculations. Same as section 8.2.1.8.

8.2.3 Dilution Interface Sampling and Analysis Procedure. Source samples that contain a high concentration of organic materials may require dilution prior to analysis to prevent saturating the GC detector. The apparatus required for this direct interface procedure is basically the same as that described in the section 8.2.2, except a dilution system is added between the heated sample line and the gas sampling valve. The apparatus is arranged so that either a 10:1 or 100:1 dilution of the source gas can be directed to the chromatograph. A pump of larger capacity is also required, and this pump must be heated and placed in the system between the sample line and the dilution apparatus.

8.2.3.1 Apparatus. The equipment required in addition to that specified for the direct interface system is as follows:

8.2.3.1.1 Sample Pump. Leakless Teflon-coated diaphragm-type that can withstand being heated to 120 °C and deliver 1.5 liters/minute.

8.2.3.1.2 Dilution Pumps. Two Model A-150 Komhyr Teflon positive displacement type delivering 150 cc/minute, or equivalent. As an option, calibrated flowmeters can be used in conjunction with Teflon-coated diaphragm pumps.

8.2.3.1.3 Valves. Two Teflon three-way valves, suitable for connecting to Teflon tubing.

8.2.3.1.4 Flowmeters. Two, for measurement of diluent gas.

8.2.3.1.5 Diluent Gas with Cylinders and Regulators. Gas can be nitrogen or clean dry air, depending on the nature of the source gases.

8.2.3.1.6 Heated Box. Suitable for being heated to 120 °C, to contain the three pumps, three-way valves, and associated connections. The box should be equipped with quick connect fittings to facilitate connection of: (1) the heated sample line from the probe, (2) the gas sampling valve, (3) the calibration gas mixtures, and (4) diluent gas lines. A schematic diagram of the components and connections is shown in Figure 18-13. The heated box shown in Figure 18-13 is designed to receive a heated line from the probe. An optional design is to build a probe unit that attaches directly to the heated box. In this way, the heated box contains the controls for the probe heaters, or, if the box is placed against the duct being sampled, it may be possible to eliminate the probe heaters. In either case, a heated Teflon line is used to connect the heated box to the gas sampling valve on the chromatograph.

NOTE: Care must be taken to leak-check the system prior to the dilutions so as not to create a potentially explosive atmosphere.

8.2.3.2 Procedure.

8.2.3.2.1 Assemble the apparatus by connecting the heated box, shown in Figure 18-13, between the heated sample line from the probe and the gas sampling valve on the chromatograph. Vent the source gas from the gas sampling valve directly to the charcoal filter, eliminating the pump and rotameter. Heat the sample probe, sample line, and heated box. Insert the probe and source thermocouple at the centroid of the duct, or to a point no closer to the walls than 1 m. Measure the source temperature, and adjust all heating units to a temperature 0 to 3 °C above this temperature. If this temperature is above the safe operating temperature of the Teflon components, adjust the heating to maintain a temperature high enough to prevent condensation of water and organic compounds (greater than 110 °C). Calibrate the GC through the dilution system by following the procedures in section 8.2.1.5.2.1. Determine the concentration of the diluted calibration gas using the dilution factor and the certified concentration of the calibration gas. Record the pertinent data on the data sheet shown in Figure 18-11.

8.2.3.2.2 Once the dilution system and GC operations are satisfactory, proceed with the analysis of source gas, maintaining the same dilution settings as used for the standards.

8.2.3.2.3 Analyze the audit samples using either the dilution system, or directly connect to the gas sampling valve as required. Record all data and report the results to the audit supervisor.

8.2.3.3 Determination of Stack Gas Moisture Content. Same as section 8.2.2.3.

8.2.3.4 Quality Assurance. Same as section 8.2.2.4.

8.2.3.5 Emission Calculations. Same as section 8.2.2.5, with the dilution factor applied.

8.2.4 Adsorption Tube Procedure. Any commercially available adsorbent is allowed for the purposes of this method, as long as the recovery study criteria in section 8.4.3 are met. Help in choosing the adsorbent may be found by calling the distributor, or the tester may refer to National Institute for Occupational Safety and Health (NIOSH) methods for the particular organics to be sampled. For some adsorbents, the principal interferent will be water vapor. If water vapor is thought to be a problem, the tester may place a midget impinger in an ice bath before the adsorbent tubes. If this option is chosen, the water catch in the midget impinger shall be analyzed for the target compounds. Also, the spike for the recovery study (in section 8.4.3) shall be conducted in both the midget impinger and the adsorbent tubes. The combined recovery (add the recovered amount in the impinger and the adsorbent tubes to calculate R) shall then meet the criteria in section 8.4.3.

NOTE: Post-test leak-checks are not allowed for this technique since this can result in sample contamination.

8.2.4.1 Additional Apparatus. The following items (or equivalent) are suggested.

8.2.4.1.1 Probe. Borosilicate glass or stainless steel, approximately 6-mm ID, with a heating system if water condensation is a problem, and a filter (either in-stack or out-of-stack, heated to stack temperature) to remove particulate matter. In most instances, a plug of glass wool is a satisfactory filter.

8.2.4.1.2 Flexible Tubing. To connect probe to adsorption tubes. Use a material that exhibits minimal sample adsorption.

8.2.4.1.3 Leakless Sample Pump. Flow controlled, constant rate pump, with a set of limiting (sonic) orifices.

8.2.4.1.4 Bubble-Tube Flowmeter. Volume accuracy within 1 percent, to calibrate pump.

8.2.4.1.5 Stopwatch. To time sampling and pump rate calibration.

8.2.4.1.6 Adsorption Tubes. Precleaned adsorbent, with mass of adsorbent to be determined by calculating breakthrough volume and expected concentration in the stack.

8.2.4.1.7 Barometer. Accurate to 5 mm Hg, to measure atmospheric pressure during sampling and pump calibration.

8.2.4.1.8 Rotameter. O to 100 cc/min, to detect changes in flow rate during sampling.

8.2.4.2 Sampling and Analysis.

8.2.4.2.1 Calibrate the pump and limiting orifice flow rate through adsorption tubes with the bubble tube flowmeter before sampling. The sample system can be operated as a “recirculating loop” for this operation. Record the ambient temperature and barometric pressure. Then, during sampling, use the rotameter to verify that the pump and orifice sampling rate remains constant.

8.2.4.2.2 Use a sample probe, if required, to obtain the sample at the centroid of the duct or at a point no closer to the walls than 1 m. Minimize the length of flexible tubing between the probe and adsorption tubes. Several adsorption tubes can be connected in series, if the extra adsorptive capacity is needed. Adsorption tubes should be maintained vertically during the test in order to prevent channeling. Provide the gas sample to the sample system at a pressure sufficient for the limiting orifice to function as a sonic orifice. Record the total time and sample flow rate (or the number of pump strokes), the barometric pressure, and ambient temperature. Obtain a total sample volume commensurate with the expected concentration(s) of the volatile organic(s) present and recommended sample loading factors (weight sample per weight adsorption media). Laboratory tests prior to actual sampling may be necessary to predetermine this volume. If water vapor is present in the sample at concentrations above 2 to 3 percent, the adsorptive capacity may be severely reduced. Operate the gas chromatograph according to the manufacturer's instructions. After establishing optimum conditions, verify and document these conditions during all operations. Calibrate the instrument and then analyze the emission samples.

8.2.4.3 Standards and Calibration. If using thermal desorption, obtain calibration gases using the procedures in section 10.1. If using solvent extraction, prepare liquid standards in the desorption solvent. Use a minimum of three different standards; select the concentrations to bracket the expected average sample concentration. Perform the calibration before and after each day's sample analyses using the procedures in section 8.2.1.5.2.1.

8.2.4.4 Quality Assurance.

8.2.4.4.1 Determine the recovery efficiency of the pollutants of interest according to section 8.4.3.

8.2.4.4.2 Determination of Sample Collection Efficiency (Optional). If sample breakthrough is thought to be a problem, a routine procedure for determining breakthrough is to analyze the primary and backup portions of the adsorption tubes separately. If the backup portion exceeds 10 percent of the total amount (primary and back-up), it is usually a sign of sample breakthrough. For the purposes of this method, only the recovery efficiency value (Section 8.4.3) is used to determine the appropriateness of the sampling and analytical procedure.

8.2.4.4.3 Volume Flow Rate Checks. Perform this check immediately after sampling with all sampling train components in place. Use the bubble-tube flowmeter to measure the pump volume flow rate with the orifice used in the test sampling, and record the result. If it has changed by more than 5 but less than 20 percent, calculate an average flow rate for the test. If the flow rate has changed by more than 20 percent, recalibrate the pump and repeat the sampling.

8.2.4.4.4 Calculations. Correct all sample volumes to standard conditions. If a sample dilution system has been used, multiply the results by the appropriate dilution ratio. Correct all results according to the applicable procedure in section 8.4.3. Report results as ppm by volume, dry basis.

8.3 Reporting of Results. At the completion of the field analysis portion of the study, ensure that the data sheets shown in Figure 18-11 have been completed. Summarize this data on the data sheets shown in Figure 18-15.

8.4 Recovery Study. After conducting the presurvey and identifying all of the pollutants of interest, conduct the appropriate recovery study during the test based on the sampling system chosen for the compounds of interest.

8.4.1 Recovery Study for Direct Interface or Dilution Interface Sampling. If the procedures in section 8.2.2 or 8.2.3 are to be used to analyze the stack gas, conduct the calibration procedure as stated in section 8.2.2.2 or 8.2.3.2, as appropriate. Upon successful completion of the appropriate calibration procedure, attach the mid-level calibration gas for at least one target compound to the inlet of the probe or as close as possible to the inlet of the probe, but before the filter. Repeat the calibration procedure by sampling and analyzing the mid-level calibration gas through the entire sampling and analytical system in triplicate. The mean of the calibration gas response sampled through the probe shall be within 10 percent of the analyzer response. If the difference in the two means is greater than 10 percent, check for leaks throughout the sampling system and repeat the analysis of the standard through the sampling system until this criterion is met.

8.4.2 Recovery Study for Bag Sampling.

8.4.2.1 Follow the procedures for the bag sampling and analysis in section 8.2.1. After analyzing all three bag samples, choose one of the bag samples and tag this bag as the spiked bag. Spike the chosen bag sample with a known mixture (gaseous or liquid) of all of the target pollutants. The theoretical concentration, in ppm, of each spiked compound in the bag shall be 40 to 60 percent of the average concentration measured in the three bag samples. If a target compound was not detected in the bag samples, the concentration of that compound to be spiked shall be 5 times the limit of detection for that compound. Store the spiked bag for the same period of time as the bag samples collected in the field. After the appropriate storage time has passed, analyze the spiked bag three times. Calculate the average fraction recovered (R) of each spiked target compound with the equation in section 12.7.

8.4.2.2 For the bag sampling technique to be considered valid for a compound, $0.70 \leq R \leq 1.30$. If the R value does not meet this criterion for a target compound, the sampling technique is not acceptable for that compound, and therefore another sampling technique shall be evaluated for acceptance (by repeating the recovery study with another sampling technique). Report the R value in the test report and correct all field measurements with the calculated R value for that compound by using the equation in section 12.8.

8.4.3 Recovery Study for Adsorption Tube Sampling. If following the adsorption tube procedure in section 8.2.4, conduct a recovery study of the compounds of interest during the actual field test. Set up two identical sampling trains. Collocate the two sampling probes in the stack. The probes shall be placed in the same horizontal plane, where the first probe tip is 2.5 cm from the outside edge of the other. One of the sampling trains shall be designated the spiked train and the other the unspiked train. Spike all of the compounds of interest (in gaseous or liquid form) onto the adsorbent tube(s) in the spiked train before sampling. The mass of each spiked compound shall be 40 to 60 percent of the mass expected to be collected with the unspiked train. Sample the stack gas into the two trains simultaneously. Analyze the adsorbents from the two trains utilizing identical analytical procedures and instrumentation. Determine the fraction of spiked compound recovered (R) using the equations in section 12.9.

8.4.3.1 Repeat the procedure in section 8.4.3 twice more, for a total of three runs. In order for the adsorbent tube sampling and analytical procedure to be acceptable for a compound, $0.70 \leq R \leq 1.30$ (R in this case is the average of three runs). If the average R value does not meet this criterion for a target compound, the sampling technique is not acceptable for that compound, and therefore another sampling technique shall be evaluated for acceptance (by repeating the recovery study with another sampling technique). Report the R value in the test report and correct all field measurements with the calculated R value for that compound by using the equation in section 12.8.

9.0 Quality Control

9.1 Miscellaneous Quality Control Measures

Section	**Quality control measure**	**Effect**
8.4.1	Recovery study for direct interface or dilution interface sampling	Ensure that there are no significant leaks in the sampling system.
8.4.2	Recovery study for bag sampling	Demonstrate that proper sampling/analysis procedures were selected.
8.4.3	Recovery study for adsorption tube sampling	Demonstrate that proper sampling/analysis procedures were selected.

10.0 Calibration and Standardization.

10.1 Calibration Standards. Obtain calibration gas standards for each target compound to be analyzed. Commercial cylinder gases certified by the manufacturer to be accurate to within 1 percent of the certified label value are preferable, although cylinder gases certified by the manufacturer to 2 percent accuracy are allowed. Another option allowed by this method is for the tester to obtain high concentration certified cylinder gases and then use a dilution system meeting the requirements of Test Method 205, 40 CFR Part 51, Appendix M to make multi-level calibration gas standards. Prepare or obtain enough calibration standards so that there are three different concentrations of each organic compound expected to be measured in the source sample. For each organic compound, select those concentrations that bracket the concentrations expected in the source samples. A calibration standard may contain more than one organic compound. If samples are collected in adsorbent tubes and extracted using solvent extraction, prepare or obtain standards in the same solvent used for the sample extraction procedure. Verify the stability of all standards for the time periods they are used.

10.2 Preparation of Calibration Curves.

10.2.1 Establish proper GC conditions, then flush the sampling loop for 30 seconds. Allow the sample loop pressure to equilibrate to atmospheric pressure, and activate the injection valve. Record the standard concentration, attenuator factor, injection time, chart speed, retention time, peak area, sample loop temperature, column temperature, and carrier gas flow rate. Analyze each standard in triplicate.

10.2.2 Repeat this procedure for each standard. Prepare a graphical plot of concentration (C_s) versus the calibration area values. Perform a regression analysis, and draw the least square line.

11.0 Analytical Procedures

11.1 Analysis Development

11.1.1 Selection of GC Parameters

11.1.1.1 Column Choice. Based on the initial contact with plant personnel concerning the plant process and the anticipated emissions, choose a column that provides good resolution and rapid analysis time. The choice of an appropriate column can be aided by a literature search, contact with manufacturers of GC columns, and discussion with personnel at the emission source.

NOTE: Most column manufacturers keep excellent records on their products. Their technical service departments may be able to recommend appropriate columns and detector type for separating the anticipated compounds, and they may be able to provide information on interferences, optimum operating conditions, and column limitations. Plants with analytical laboratories may be able to provide information on their analytical procedures.

11.1.1.2 Preliminary GC Adjustment. Using the standards and column obtained in section 11.1.1.1, perform initial tests to determine appropriate GC conditions that provide good resolution and minimum analysis time for the compounds of interest.

11.1.1.3 Preparation of Presurvey Samples. If the samples were collected on an adsorbent, extract the sample as recommended by the manufacturer for removal of the compounds with a solvent suitable to the type of GC analysis. Prepare other samples in an appropriate manner.

11.1.1.4 Presurvey Sample Analysis.

11.1.1.4.1 Before analysis, heat the presurvey sample to the duct temperature to vaporize any condensed material. Analyze the samples by the GC procedure, and compare the retention times against those of the calibration samples that contain the components expected to be in the stream. If any compounds cannot be identified with certainty by this procedure, identify them by other means such as GC/mass spectroscopy (GC/MS) or GC/infrared techniques. A GC/MS system is recommended.

11.1.1.4.2 Use the GC conditions determined by the procedure of section 11.1.1.2 for the first injection. Vary the GC parameters during subsequent injections to determine the optimum settings. Once the optimum settings have been determined, perform repeat injections of the sample to determine the retention time of each compound. To inject a sample, draw sample through the loop at a constant rate (100 ml/min for 30 seconds). Be careful not to pressurize the gas in the loop. Turn off the pump and allow the gas in the sample loop to come to ambient pressure. Activate the sample valve, and record injection time, loop temperature, column temperature, carrier flow rate, chart speed, and attenuator setting. Calculate the retention time of each peak using the distance from injection to the peak maximum divided by the chart speed. Retention times should be repeatable within 0.5 seconds.

11.1.1.4.3 If the concentrations are too high for appropriate detector response, a smaller sample loop or dilutions may be used for gas samples, and, for liquid samples, dilution with solvent is appropriate. Use the standard curves (Section 10.2) to obtain an estimate of the concentrations.

11.1.1.4.4 Identify all peaks by comparing the known retention times of compounds expected to be in the retention times of peaks in the sample. Identify any remaining unidentified peaks which have areas larger than 5 percent of the total using a GC/MS, or estimation of possible compounds by their retention times compared to known compounds, with confirmation by further GC analysis.

12.0 Data Analysis and Calculations

12.1 Nomenclature.

B_{ws} = Water vapor content of the bag sample or stack gas, proportion by volume.

C_s = Concentration of the organic from the calibration curve, ppm.

G_v = Gas volume or organic compound injected, ml.

L_v = Liquid volume of organic injected, µl.

M = Molecular weight of organic, g/g-mole.

m_s = Total mass of compound measured on adsorbent with spiked train (µg).

m_u = Total mass of compound measured on adsorbent with unspiked train (µg).

m_v = Mass per volume of spiked compound measured (µg/L).

P_i = Barometric or absolute sample loop pressure at time of sample analysis, mm Hg.

P_m = Absolute pressure of dry gas meter, mm Hg.

P_r = Reference pressure, the barometric pressure or absolute sample loop pressure recorded during calibration, mm Hg.

P_s = Absolute pressure of syringe before injection, mm Hg.

q_c = Flow rate of the calibration gas to be diluted.

q_{c1} = Flow rate of the calibration gas to be diluted in stage 1.

q_{c2} = Flow rate of the calibration gas to be diluted in stage 2.

q_d = Diluent gas flow rate.

q_{d1} = Flow rate of diluent gas in stage 1.

q_{d2} = Flow rate of diluent gas in stage 2.

s = Theoretical concentration (ppm) of spiked target compound in the bag.

S = Theoretical mass of compound spiked onto adsorbent in spiked train (µg).

t = Measured average concentration (ppm) of target compound and source sample (analysis results subsequent to bag spiking)

T_i = Sample loop temperature at the time of sample analysis, °K.

T_m = Absolute temperature of dry gas meter, °K.

T_s = Absolute temperature of syringe before injection, °K.

u = Source sample average concentration (ppm) of target compound in the bag (analysis results before bag spiking).

V_m=Gas volume indicated by dry gas meter, liters.

v_s = volume of stack gas sampled with spiked train (L).

v_u = volume of stack gas sampled with unspiked train (L).

X = Mole or volume fraction of the organic in the calibration gas to be diluted.

Y = Dry gas meter calibration factor, dimensionless.

µl = Liquid organic density as determined, g/ml.

24.055 = Ideal gas molar volume at 293 °K and 760 mm Hg, liters/g-mole.

1000 = Conversion factor, ml/liter.

10^6 = Conversion to ppm.

12.2 Calculate the concentration, C_s, in ppm using the following equation:

$$C_s = \frac{10^6 \left(\bar{X} q_c\right)}{q_c + q_d} \qquad \text{Eq. 18-1}$$

12.3 Calculate the concentration, C_s, in ppm of the organic in the final gas mixture using the following equation:

$$C_s = 10^6 \bar{X} \left(\frac{q_{c1}}{q_{c1} + q_{d1}} \right) \left(\frac{q_{c2}}{q_{c2} + q_{d2}} \right) \qquad \text{Eq. 18-2}$$

12.4 Calculate each organic standard concentration, C_s, in ppm using the following equation:

$$C_s = \frac{G_v \times 10^6 \dfrac{293}{T_s} \dfrac{P_s}{760}}{V_m Y \dfrac{293}{T_m} \dfrac{P_m}{760} 1000} \qquad \text{Eq. 18-3}$$

$$= \frac{G_v \times 10^3 \dfrac{P_s}{T_s} \dfrac{T_m}{P_m}}{V_m Y}$$

12.5 Calculate each organic standard concentration, C_s, in ppm using the following equation:

$$C_s = \frac{\dfrac{L_v}{M} \rho \left(24.055 \times 10^6 \right)}{V_m Y \dfrac{293}{T_m} \dfrac{P_m}{760} 1000} = 6.24 \times 10^4 \frac{L_v \rho T_m}{M V_m Y P_m} \qquad \text{Eq. 18-4}$$

12.6 Calculate the concentration, C_c, in ppm, dry basis, of each organic is the sample using the following equation:

$$C_C = \frac{C_S P_r T_i F_r}{P_i T_r (1 - B_{ws})} \qquad \text{Eq. 18-5}$$

12.7 Calculate the average fraction recovered (R) of each spiked target compound using the following equation:

$$R = \frac{t - u}{s} \qquad \text{Eq. 18-6}$$

12.8 Correct all field measurements with the calculated R value for that compound using the following equation:

$$\text{Reported Result} = \frac{\text{Measured Concentration (ppm)}}{\text{R}} \qquad \text{Eq. 18-7}$$

12.9 Determine the mass per volume of spiked compound measured using the following equation:

$$m_v = \frac{m_s}{V_s} - \frac{m_u}{V_u} \qquad \text{Eq. 18-8}$$

12.10 Calculate the fraction of spiked compound recovered, R, using the following equation:

$$R = \frac{m_v \times v_s}{S} \qquad \text{Eq. 18-9}$$

13.0 Method Performance

13.1 Since a potential sample may contain a variety of compounds from various sources, a specific precision limit for the analysis of field samples is impractical. Precision in the range of 5 to 10 percent relative standard deviation (RSD) is typical for gas chromatographic techniques, but an experienced GC operator with a reliable instrument can readily achieve 5 percent RSD. For this method, the following combined GC/operator values are required.

(a) Precision. Triplicate analyses of calibration standards fall within 5 percent of their mean value.

(c) Recovery. After developing an appropriate sampling and analytical system for the pollutants of interest, conduct the procedure in section 8.4. Conduct the appropriate recovery study in section 8.4 at each sampling point where the method is being applied. Submit the data and results of the recovery procedure with the reporting of results under section 8.3.

14.0 Pollution Prevention [Reserved]

15.0 Waste Management [Reserved]

16.0 Alternative Procedures

16.1 Optional Presurvey and Presurvey Sampling.

NOTE: Presurvey screening is optional. Presurvey sampling should be conducted for sources where the target pollutants are not known from previous tests and/or process knowledge.

Perform a presurvey for each source to be tested. Refer to Figure 18-1. Some of the information can be collected from literature surveys and source personnel. Collect gas samples that can be analyzed to confirm the identities and approximate concentrations of the organic emissions.

16.1.1 Apparatus. This apparatus list also applies to sections 8.2 and 11.

16.1.1.1 Teflon Tubing. (Mention of trade names or specific products does not constitute endorsement by the U.S. Environmental Protection Agency.) Diameter and length determined by connection requirements of cylinder regulators and the GC. Additional tubing is necessary to connect the GC sample loop to the sample.

16.1.1.2 Gas Chromatograph. GC with suitable detector, columns, temperature-controlled sample loop and valve assembly, and temperature programmable oven, if necessary. The GC shall achieve sensitivity requirements for the compounds under study.

16.1.1.3 Pump. Capable of pumping 100 ml/min. For flushing sample loop.

16.1.1.4 Flow Meter. To measure flow rates.

16.1.1.5 Regulators. Used on gas cylinders for GC and for cylinder standards.

16.1.1.6 Recorder. Recorder with linear strip chart is minimum acceptable. Integrator (optional) is recommended.

16.1.1.7 Syringes. 0.5-ml, 1.0- and 10-microliter size, calibrated, maximum accuracy (gas tight) for preparing calibration standards. Other appropriate sizes can be used.

16.1.1.8 Tubing Fittings. To plumb GC and gas cylinders.

16.1.1.9 Septa. For syringe injections.

16.1.1.10 Glass Jars. If necessary, clean, colored glass jars with Teflon-lined lids for condensate sample collection. Size depends on volume of condensate.

16.1.1.11 Soap Film Flowmeter. To determine flow rates.

16.1.1.12 Flexible Bags. Tedlar or equivalent, 10- and 50-liter capacity, for preparation of standards. (Verify through the manufacturer that the Tedlar alternative is suitable for the compound of interest and make this verifying information available for inspection.)

16.1.1.13 Dry Gas Meter with Temperature and Pressure Gauges. Accurate to ±2 percent, for preparation of gas standards.

16.1.1.14 Midget Impinger/Hot Plate Assembly. For preparation of gas standards.

16.1.1.15 Sample Flasks. For presurvey samples, must have gas-tight seals.

16.1.1.16 Adsorption Tubes. If necessary, blank tubes filled with necessary adsorbent (charcoal, Tenax, XAD-2, etc.) for presurvey samples.

16.1.1.17 Personnel Sampling Pump. Calibrated, for collecting adsorbent tube presurvey samples.

16.1.1.18 Dilution System. Calibrated, the dilution system is to be constructed following the specifications of an acceptable method.

16.1.1.19 Sample Probes. Pyrex or stainless steel, of sufficient length to reach centroid of stack, or a point no closer to the walls than 1 m.

16.1.1.20 Barometer. To measure barometric pressure.

16.1.2 Reagents.

16.1.2.1 Water. Deionized distilled.

16.1.2.2 Methylene chloride.

16.1.2.3 Calibration Gases. A series of standards prepared for every compound of interest.

16.1.2.4 Organic Compound Solutions. Pure (99.9 percent), or as pure as can reasonably be obtained, liquid samples of all the organic compounds needed to prepare calibration standards.

16.1.2.5 Extraction Solvents. For extraction of adsorbent tube samples in preparation for analysis.

16.1.2.6 Fuel. As recommended by the manufacturer for operation of the GC.

16.1.2.7 Carrier Gas. Hydrocarbon free, as recommended by the manufacturer for operation of the detector and compatibility with the column.

16.1.2.8 Zero Gas. Hydrocarbon free air or nitrogen, to be used for dilutions, blank preparation, and standard preparation.

16.1.3 Sampling.

16.1.3.1 Collection of Samples with Glass Sampling Flasks. Presurvey samples may be collected in precleaned 250-ml double-ended glass sampling flasks. Teflon stopcocks, without grease, are preferred. Flasks should be cleaned as follows: Remove the stopcocks from both ends of the flasks, and wipe the parts to remove any grease. Clean the stopcocks, barrels, and receivers with methylene chloride (or other non-target pollutant solvent, or heat and humidified air). Clean all glass ports with a soap solution, then rinse with tap and deionized distilled water. Place the flask in a cool glass annealing furnace, and apply heat up to 500 °C. Maintain at this temperature for 1 hour. After this time period, shut off and open the furnace to allow the flask to cool. Return the stopcocks to the flask receivers. Purge the assembly with high-purity nitrogen for 2 to 5 minutes. Close off the stopcocks after purging to maintain a slight positive nitrogen pressure. Secure the stopcocks with tape. Presurvey samples can be obtained either by drawing the gases into the previously evacuated flask or by drawing the gases into and purging the flask with a rubber suction bulb.

16.1.3.1.1 Evacuated Flask Procedure. Use a high-vacuum pump to evacuate the flask to the capacity of the pump; then close off the stopcock leading to the pump. Attach a 6-mm outside diameter (OD) glass tee to the flask inlet with a short piece of Teflon tubing. Select a 6-mm OD borosilicate sampling probe, enlarged at one end to a 12-mm OD and of sufficient length to reach the centroid of the duct to be sampled. Insert a glass wool plug in the enlarged end of the probe to remove particulate matter. Attach the other end of the probe to the tee with a short piece of Teflon tubing. Connect a rubber suction bulb to the third leg of the tee. Place the filter end of the probe at the centroid of the duct, and purge the probe with the rubber suction bulb. After the probe is completely purged and filled with duct gases, open the stopcock to the grab flask until the pressure in the flask reaches duct pressure. Close off the stopcock, and remove the probe from the duct. Remove the tee from the flask and tape the stopcocks to prevent leaks during shipment. Measure and record the duct temperature and pressure.

16.1.3.1.2 Purged Flask Procedure. Attach one end of the sampling flask to a rubber suction bulb. Attach the other end to a 6-mm OD glass probe as described in section 8.3.3.1.1. Place the filter end of the probe at the centroid of the duct, or at a point no closer to the walls than 1 m, and apply suction with the bulb to completely purge the probe and flask. After the flask has been purged, close off the stopcock near the suction bulb, and then close off the stopcock near the probe. Remove the probe from the duct, and disconnect both the probe and suction bulb. Tape the stopcocks to prevent leakage during shipment. Measure and record the duct temperature and pressure.

16.1.3.2 Flexible Bag Procedure. Any leak-free plastic (e.g., Tedlar, Mylar, Teflon) or plastic-coated aluminum (e.g., aluminized Mylar) bag, or equivalent, can be used to obtain the pre-survey sample. Use new bags, and leak-check them before field use. In addition, check the bag before use for contamination by filling it with nitrogen or air and analyzing the gas by GC at high sensitivity. Experience indicates that it is desirable to allow the inert gas to remain in the bag about 24 hours or longer to check for desorption of organics from the bag. Follow the leak-check and sample collection procedures given in Section 8.2.1.

16.1.3.3 Determination of Moisture Content. For combustion or water-controlled processes, obtain the moisture content from plant personnel or by measurement during the presurvey. If the source is below 59 °C, measure the wet bulb and dry bulb temperatures, and calculate the moisture content using a psychrometric chart. At higher temperatures, use Method 4 to determine the moisture content.

16.1.4 Determination of Static Pressure. Obtain the static pressure from the plant personnel or measurement. If a type S pitot tube and an inclined manometer are used, take care to align the pitot tube 90° from the direction of the flow. Disconnect one of the tubes to the manometer, and read the static pressure; note whether the reading is positive or negative.

16.1.5 Collection of Presurvey Samples with Adsorption Tube. Follow section 8.2.4 for presurvey sampling.

Attenuation factor			
Peak height (mm)			
Peak area (mm^2)			
Peak area * attenuation factor (mm^2)			
Calculated concentration (ppm) (Equation 18-3 or 18-4)			

Plot peak area * attenuation factor against calculated concentration to obtain calibration curve.

Flowmeter number or identification ____
Flowmeter Type ____
Method: Bubble meter___________ Spirometer_______________ Wet test meter ___________
Readings at laboratory conditions:
Laboratory temperature (T_{lab}) ________________ °K
Laboratory barometric pressure (P_{lab})___________ mm Hg

Flow data:

FLOWMETER

Reading (as marked)	Temp. (°K)	Pressure (absolute)

CALIBRATION DEVICE

Time (min)	Gas volume[a]	Flow rate[b]

[a]Vol. of gas may be measured in milliliters, liters or cubic feet.
[b]Convert to standard conditions (20 °C and 760 mm Hg). Plot flowmeter reading against flow rate (standard conditions), and draw a smooth curve. If the flowmeter being calibrated is a rotameter or other flow device that is viscosity dependent, it may be necessary to generate a "family" of calibration curves that cover the operating pressure and temperature ranges of the flowmeter. While the following technique should be verified before application, it may be possible to calculate flow rate reading for rotameters at standard conditions Q_{std} as follows:

$$Q_{std} = Q_{lab}\left(\frac{760 \times T_{lab}}{P_{lab} \times 293}\right)^{1/2}$$

Flow rate (laboratory conditions)	Flow rate (STD conditions)
